INTRODUCTION

Motivation for verifying systems

Era of scale—enter proof engineering [75]

Looking back (Social Processes [33]), development has come a long way, but maintenance is still hard! And this is a problem in practice!

But missed opportunity: automation doesn't understand that proofs evolve

So we build automation that does, and we call this proof repair. Proof repair shows that there is reason to believe that verifying a modified system should often, in practical use cases, be easier than verifying the original the first time around.

Or, in other words (thesis statement): Changes in programs, specifications, and proofs carry information that a tool can extract, generalize, and apply to fix other proofs broken by the same change. A tool that automates this can save work for proof engineers relative to reference manual repairs in practical use cases.

Key technical bit: differencing and program transformations, taking advantage of the rich and structured language proofs are written in.

We implement this in a tool suite for Coq, get some sweet results.

Pave path to the next era of verification

2

MOTIVATING PROOF REPAIR

Before we talk more about proof repair, it helps to know what it's like to develop and maintain proofs to begin with, and what happens under the hood when you do that. This chapter gives you that context, then explains the high-level approach to proof repair that builds on that.

2.1 PROOF DEVELOPMENT

Cartoon version of development: program, spec, proof

Proof assistants: short overview of foundations & different options (survey paper), then say focus on Coq

Slightly less brief overview of Coq and its foundations and automation and so on (including proof terms), going through a running example of proof development in Coq

2.2 PROOF MAINTENANCE

Problem is when something changes—change something in running example

There are a lot of development processes people use to make proofs less likely to break to begin with (survey paper)

But still, even with these, the reality: This happens all the time (REPLICA)

And in fact not just after developing a proof, but during development too (REPLICA)

And breaks proofs even for experts (REPLICA)

And it's an extra big problem when you have a large development and the changes are outside of your control

Hence Social Processes

Why automation breaks, even with good development processes

Hence proof repair—smarter automation

2.3 PROOF REPAIR

Name inspired by program repair, but quite different as we'll soon see.

Recall thesis: Changes in programs, specifications, and proofs carry information that a tool can extract, generalize, and apply to fix other proofs broken by the same change. A tool that automates this can save work for proof engineers relative to reference manual repairs in practical use cases.

Proof repair accomplishes this using a combination of differencing and program transformations.

Differencing extracts the information from the change in program, specification, or proof.

The transformations then generalize that information to a more general fix for other proofs broken by the same change.

The details of applying the fix vary by the kind of fix, as we'll soon see.

Crucially, all of this happens over the proof terms in this rich language we saw in the Development section. This is kind of the key insight that makes it all work.

This is great because this language gives us so much information and certainty. This helps us with two of the biggest challenges from program repair. (generals related work)

But it's also challenging because this language is so unforgiving. Plus, in the end, we need these tactic proofs, not just proof terms. So we can't just reuse program repair tools. (generals related work)

So next two chapters will show two tools in our tool suite that work this way, how they handle these challenges, and how they save work.

3

PROOF REPAIR BY EXAMPLE

The first tool (PUMPKIN PATCH) focuses on changes in programs and specifications, though these changes are limited in scope as we'll see later.

What this tool does is, when programs and specifications change and this breaks a lot of proofs, it lets the proof engineer fix just one of those proofs. It then generalizes the example patch into something that can fix other proofs broken by the same change.

So in other words, the information from those changes is carried in the difference between the old and new version of the example patched proof. PUMPKIN PATCH generalizes that information.

Application can be automated in some cases at the end, or it can be manual.

The work saved is shown retroactively on case studies replaying changes from large proof devleopments in Git. Results for this tool are preliminary compared to what we'll see later, since this was the first prototype.

3.1 MOTIVATING EXAMPLE

Traditional proof automation considers only the current state of theorems, proofs, and definitions. This is a missed opportunity: verification projects are rarely static. Like other software, these projects evolve over time.

With traditional proof automation, the burden of change largely falls on proof engineers. This does not have to be true. Proof automation can view theorems, proofs, and definitions as fluid entities: when a proof or specification changes, a tool can search the difference between the old and new versions for a *reusable patch* that can fix broken proofs.

WITHOUT PROOF REPAIR Experienced Coq programmers use design principles and custom tactics to make proofs resilient to change. These techniques are useful for large proof developments, but they place the burden of change on the programmer. This can be problematic when change occurs outside of the programmer's control.

```
Definition IZR (z:Z) : R :=
  match z with
  | Z0 => 0
  | Zpos n => INR (Pos.to_nat n)
  | Zneg n => - INR (Pos.to_nat n)
  end.
```

```
Definition IZR (z:Z) : R :=
  match z with
  | Z0 => 0
  | Zpos n => IPR n
  | Zneg n => - IPR n
  end.
```

Figure 1: Old (left) and new (right) definitions of IZR in Coq. The old definition applies injection from naturals to reals and conversion of positives to naturals; the new definition applies injection from positives to reals.

Consider a commit from the Coq 8.7 release [62]. This commit redefined injection from integers to reals (Figure 1). This change broke 18 proofs in the standard library.

The Coq developer who committed the change fixed the broken proofs, then made an additional 12 commits to address the change in `coq-contribs`, a regression suite of projects that the Coq developers maintain as versions change. Many of these changes were simple. For example, the developer wrote a lemma that describes the change:

```
Lemma INR_IPR : ∀p, INR (Pos.to_nat p) = IPR p.
```

The developer then used this lemma to fix broken proofs within the standard library. For example, one proof broke on this line:

```
rewrite Pos2Nat.inj_sub by trivial.✗
```

It succeeded with the lemma:

```
rewrite <- 3!INR_IPR, Pos2Nat.inj_sub by trivial.✓
```

These changes are outside-facing: Coq users have to make similar changes to their own proofs when they update from Coq 8.6 to Coq 8.7. The Coq developer can update some tactics to account for this, but it is impossible to account for every tactic that users could use. Furthermore, while the developer responsible for the changes knows about the lemma that describes the change, the Coq user does not. The Coq user must determine how the definition has changed and how to address the change, perhaps by reading documentation or by talking to the developers.

WITH PROOF REPAIR When a user updates the Coq standard library, a proof repair tool can determine that the definition has changed, then analyze changes in the standard library and in `coq-contribs` that resulted from the change in definition (in this case, rewriting by the lemma). It can extract a reusable patch from those changes, which it can automatically apply within broken user proofs. The user never has to consider how the definition has changed.

3.2 APPROACH

In the example from Section 3.1, we can see how the example change in one proof carries enough information to fix other proofs broken by the same change (namely the rewrite by `INR\_IPR`). So a tool can extract that, generalize it, and use it to fix other proofs broken by the same change.

The key insight behind PUMPKIN's approach is that this is true more generally. To use PUMPKIN, the programmer modifies a single proof script to provide an *example* of how to adapt a proof to a change. PUMPKIN extracts that information into a *patch candidate*—which is localized to the context of the example, but not enough to fix other proofs broken by the change. It then generalizes that candidate into a *reusable patch*: a function that can be used to fix other broken proofs broken by the same change, which PUMPKIN defines as a Coq term.

In other words, looking back to the thesis statement, the information shows up in the difference between versions of the example patched proof. PUMPKIN can extract and generalize that information. Application works with hint databases or is manual. Here is the system diagram for PUMPKIN. The PUMPKIN repository contains a detailed user guide.

As mentioned earlier, PUMPKIN does this using a combination of semantic differencing and program transformations. Differencing looks at the difference between versions of the example patched proof for this information, and finds the candidate. Then, program transformations modify that candidate to produce the reusable proof patch.

And of course all of this happens over proof terms, since tactics might hide necessary in information. Of course this is hard to see on the example from Section 3.1, since we were lucky enough to see the difference in tactics here. Let's look at a toy example for which that isn't true.

To motivate this workflow, consider using PUMPKIN to search the proofs in Figure 2 for a patch between conclusions. Except we will show a place where the lemma is actually applied. Note that the tactics don't change even though the terms do—and even though the change could break other proofs.

So what do we do? We invoke the plugin using `old` and `new` as the example change:

```
Patch Proof old new as patch.
```

PUMPKIN first determines the type that a patch from `new` to `old` should have. To determine this, it semantically *diffs* the types and finds this goal type (line 2):

```
∀ n m p, n <= m -> m <= p -> n <= p -> n <= p + 1
```

It then breaks each inductive proof into cases and determines an intermediate goal type for the candidate. In the base case, for example,

```
Theorem old: ∀ (n m p : nat),
  n <= m -> m <= p ->
  n <= p + 1.                        (* P p *)
Proof.
  intros. induction H0.
  - auto with arith.
  - constructor. auto.
Qed.

fun (n m p : nat) (H : n <= m) (H0 : m <= p) =>
  le_ind
    m                                (* m *)
    (fun p0 => n <= p0 + 1)          (* P *)
    (le_plus_trans n m 1 H)          (* : P m *)
    (fun (m0 : nat) (_ : m <= m0) (IHle : n <= m0 + 1) =>
      le_S n (m0 + 1) IHle)
    p                                (* p *)
    H0
```

```
Theorem new: ∀ (n m p : nat), n <= m -> m <= p ->
  n <= p.                            (* P' p *)
Proof.
  intros. induction H0.
  - auto with arith.
  - constructor. auto.
Qed.

fun (n m p : nat) (H : n <= m) (H0 : m <= p) =>
  le_ind
    m                                (* m *)
    (fun p0 => n <= p0)              (* P' *)
    H                                (* : P' m *)
    (fun (m0 : nat) (_ : m <= m0) (IHle : n <= m0) =>
      le_S n m0 IHle)
    p                                (* p *)
    H0
```

Figure 2: Two proofs with different conclusions (top) and the corresponding proof terms (bottom) with relevant type information. We highlight the change in theorem conclusion and the difference in terms that corresponds to a patch.

it *diffs* the types and determines that a candidate between the base cases of `new` and `old` should have this type (lines 11 and 12):

```
(fun p0 => n <= p0) m -> (fun p0 => n <= p0 + 1) m
```

It then *diffs* the terms (line 13) for such a candidate:

```
fun n m p H0 H1 =>
  (fun (H : n <= m) => le_plus_trans n m 1 H)
: ∀ n m p, n <= m -> m <= p -> n <= m -> n <= m + 1
```

This candidate is close, but it is not yet a patch. This candidate maps base case to base case (it is applied to `m`); the patch should map conclusion to conclusion (it should be applied to `p`).

This is where the transformations come in. There are four:

1. *Patch specialization* to arguments
2. *Patch abstraction* of arguments or functions
3. *Patch inversion* to reverse a patch
4. *Lemma factoring* to break a term into parts

Here, Pumpkin *abstracts* this candidate by `m` (line 11), which lifts it out of the base case:

```
fun n0 n m p H0 H1 =>
  (fun (H : n <= n0) => le_plus_trans n n0 1 H)
: ∀ n0 n m p, n <= m -> m <= p -> n <= n0 -> n <= n0 + 1
```

Pumpkin then *specializes* this candidate to `p` (line 16), the argument to the conclusion of `le_ind`. This produces a patch:

```
patch n m p H0 H1 :=
  (fun (H : n <= p) => le_plus_trans n p 1 H)
: ∀ n m p, n <= m -> m <= p -> n <= p -> n <= p + 1
```

The user can then use `patch` to fix other broken proofs. For example, given a proof that applies `old`, the user can use `patch` to prove the same conclusion by applying `new`:

```
apply old.✓
apply patch. apply new.✓
```

This can happen automatically through hint databases.

This simple example uses only two transformations. The other transformations help turn candidates into patches in similar ways. We discuss all of this in detail later.

configuration The components come together to form a proof patch finding procedure:

Pseudocode: find_patch(term, term', direction)

```
diff types of term and term' for goals
diff term and term' for candidates
if there are candidates then
    factor, abstract, specialize, and/or invert candidates
    if there are patches then return patches
return failure
```

PUMPKIN infers a *configuration* from the example change. This configuration customizes the highlighted lines for an entire class of changes: It determines what to diff on lines 1 and 2, and how to use the components on line 4.

For example, to find a patch for Figure 2, PUMPKIN used the configuration for changes in conclusions of two proofs that induct over the same hypothesis. Given two such proofs:

```
∀ x, H x -> P x
∀ x, H x -> P' x
```

PUMPKIN searches for a patch with this type:

```
∀ x, H x -> P' x -> P x
```

using this configuration:

```
1: diff conclusion types for goals
2: diff conclusion terms for candidates
3: if there are candidates then
4:     abstract and then specialize candidates
```

Later we will see real-world examples that demonstrate more configurations.

3.3 DIFFERENCING

The tool should be able to identify the semantic difference between terms. The semantic difference is the difference between two terms that corresponds to the difference between their types. Consider the base case terms in Figure 2 (line 13):

```
le_plus_trans n m 1 H : n <= m + 1
                    H : n <= m
```

The semantic differencing component first identifies the difference in their types, or the *goal type*:

```
n <= m -> n <= m + 1
```

It then finds a difference in terms that has that type:

```
fun (H : n <= m) => le_plus_trans n m 1 H
```

This is the *candidate* for a reusable patch that the other components modify to find a patch.

Differencing operates over terms and types. Differencing tactics is insufficient, since tactics and hints may mask patches (line 5).[1] Furthermore, differencing is aware of the semantics of terms and types. Simply exploring the syntactic difference makes it hard to identify which changes are meaningful. For example, in the inductive case (line 14), the inductive hypothesis changes:

```
... (IHle : n <= m0 + 1) ...
... (IHle : n <= m0) ...
```

1 Since this is a simple example, replaying an existing tactic happens to work. There are additional examples in the repository (`Cex.v`).

However, the type of `IHle` changes for *any* two inductive proofs over `le` with different conclusions. A syntactic differencing component may identify this change as a candidate. Our semantic differencing component knows that it can ignore this change.

Plus parts of Inside the Core, Testing Boundaries, Future Work

How differencing works in detail

Limitations and whether they're addressed in later tools yet or not

3.4 TRANSFORMATION

PATCH SPECIALIZATION The tool should be able to specialize a patch candidate to specific arguments as determined by the differences in terms. To find a patch for Figure 2, for example, PUMPKIN must specialize the patch candidate to `p` to produce the final patch.

PATCH ABSTRACTION A tool should be able to abstract patch candidates of this form by the common argument:

```
candidate : P' t -> P t
candidate_abs : ∀ t0, P' t0 -> P t0
```

and it should be able to abstract patch candidates of this form by the common function:

```
candidate : P t' -> P t
candidate_abs : ∀ P0, P0 t' -> P0 t
```

This is necessary because the tool may find candidates in an applied form. For example, when searching for a patch between the proofs in Figure 2, PUMPKIN finds a candidate in the difference of base cases. To produce a patch, PUMPKIN must abstract the candidate by the argument `m`. Abstracting candidates is not always possible; abstraction will necessarily be a collection of heuristics.

PATCH INVERSION The tool should be able to invert a patch candidate. This is necessary to search for isomorphisms. It is also necessary to search for implications between propositionally equal types, since candidates may appear in the wrong direction. For example, consider two list lemmas (we write `length` as `len`):

```
old : ∀ l' l, len (l' ++ l) = len l' + len l
new : ∀ l' l, len (l' ++ l) = len l' + len (rev l)
```

If PUMPKIN searches the difference in proofs of these lemmas for a patch from the conclusion of `new` to the conclusion of `old`, it may find a candidate *backwards*:

```
candidate l' l (H : old l' l) :=
  eq_ind_r ... (rev_length l)
: ∀ l' l, old l' l -> new l' l
```

The component can invert this to get the patch:

```
patch l' l (H : new l' l) :=
  eq_ind_r ... (eq_sym (rev_length l))
: ∀ l' l, new l' l -> old l' l
```

We can then use this patch to port proofs. For example, if we add this patch to a hint database [1], we can port this proof:

```
Theorem app_rev_len : ∀ l l',
  len (rev (l' ++ l)) = len (rev l) + len (rev l').
Proof.
  intros. rewrite rev_app_distr. apply old.✓
Qed.
```

to this proof:

```
Theorem app_rev_len : ∀ l l',
  len (rev (l' ++ l)) = len (rev l) + len (rev l').
Proof.
  intros. rewrite rev_app_distr. apply new.✓
Qed.
```

Rewrites like `candidate` are *invertible*: We can invert any rewrite in one direction by rewriting in the opposite direction. In contrast, it is not possible to invert the patch PUMPKIN found for Figure 2. Inversion will necessarily sometimes fail, since not all terms are invertible.

LEMMA FACTORING The tool should be able to factor a term into a sequence of lemmas. This can help break other problems, like abstraction, into smaller subproblems. It is also necessary to invert certain terms. Consider inverting an arbitrary sequence of two rewrites:

```
t := eq_ind_r G ... (eq_ind_r F ...)
```

We can view `t` as a term that composes two functions:

```
g := eq_ind_r G ...
f := eq_ind_r F ...
t := g ∘ f
```

The inverse of `t` is the following:

```
t⁻¹ := f⁻¹ ∘ g⁻¹
```

To invert `t`, PUMPKIN identifies the factors `[f; g]`, inverts each factor to `[f⁻¹; g⁻¹]`, then folds and applies the inverse factors in the opposite direction.

plus parts of PUMPKIN PATCH Inside the Core, Testing Boundaries, Future Work

How the four transformations work in detail

Limitations and whether they're addressed in later tools yet or not

3.5 IMPLEMENTATION

parts of PUMPKIN PATCH Inside the Core, plus more

3.5.1 *Tool Details*

While our system is a very early prototype under active development, we have made the source code available on Github.[2] The interested

2 http://github.com/uwplse/PUMPKIN-PATCH/tree/cpp18

reader can follow along in the repository. Our prototype has no impact on the trusted computing base (Section 3.5.2.1).

3.5.1.1 *Semantic Differencing*

We implement semantic differencing over *trees*: PUMPKIN compiles each proof term into a tree (`evaluation.ml`). In these trees, every node is a type context, and every edge is an extension to that type context with a new term.[3] Correspondingly, type differencing (to identify goal types) compares nodes, and term differencing (to find candidates) compares edges.

The component (`differencing.ml`) uses these nodes and edges to prioritize semantically relevant differences. At the lowest level, it calls a primitive differencing function which checks if it can substitute one term within another term to find a function between their types.

The key benefit to this model is that it gives us a natural way to express inductive proofs, so that differencing can efficiently identify good candidates. Consider, for example, searching for a patch between conclusions of two inductive proofs of theorems about the natural numbers:

```
nat_ind P ... (fun (IH : P n) => ...) : ∀ n, P n
nat_ind P' ... (fun (IH : P' n) => ...) : ∀ n, P' n
```

In each case, the component diffs the terms in the dotted edges of the tree for `nat_ind` (Figure 3) to try to find a term that maps between conclusions of that case:

```
P' 0 -> P 0         (* base case candidate *)
P' (S n) -> P (S n) (* inductive case candidate *)
```

The component also knows that the change in the type of `IH` is inconsequential (it occurs for any change in conclusion). Furthermore, it knows that `IH` cannot show up as a hypothesis in the patch, so it attempts to remove any occurrences of `IH` in any candidate.

When the component finds a candidate, it knows `P'` and `P` as well as the arguments `0` or `(S n)`. This makes it simple to query abstraction for the final patch:

```
∀ n, P' n -> P n
```

The differencing component is *lazy*: it compiles terms into trees one step at a time. It then *expands* each tree as needed to find candidates (`expansion.ml`). For example, consider searching two functions for a patch between conclusions:

```
fun (t : T) => b
fun (t' : T) => b'
```

Differencing introduces a single term of type `T` to a common environment, then expands and recursively diffs the bodies `b` and `b'` in that environment.

3 These trees are inspired by categorical models of dependent type theory [42].

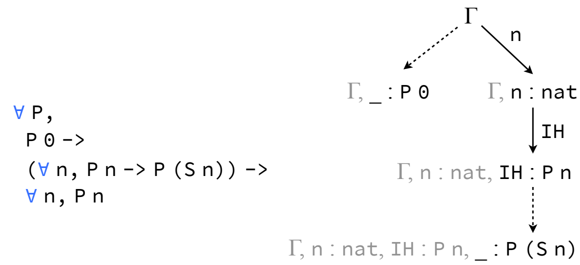

Figure 3: The type of (left) and tree for (right) the induction principle `nat_ind`. The solid edges represent hypotheses, and the dotted edges represent the proof obligations for each case in an inductive proof.

The tool always maintains pointers to easily switch between the tree and AST representations of the terms. This representation enables extensibility.

3.5.1.2 *Transformations*

PATCH SPECIALIZATION Specialization (`specialize.ml`) takes a patch candidate and some arguments, all of which are Coq terms. It applies the candidate to the arguments, then it $\beta\iota$-reduces [19] the result using Coq's `Reduction.nf_betaiota` function. It is the job of the patch finding procedure to provide both the candidate and the arguments.

PATCH ABSTRACTION Abstraction (`abstraction.ml`) takes a patch candidate, the goal type, and the function arguments or function to abstract. It first generalizes the candidate, wrapping it inside of a lambda from the type of the term to abstract. Then, it substitutes terms inside the body with the abstract term. It continues to do this until there is nothing left to abstract, then filters results by the goal type. Consider, for example, abstracting this candidate by `m`:

```
fun (H : n <= m) => le_plus_trans n m 1 H
: n <= m -> n <= m + 1
```

The generalization step wraps this in a lambda from some `nat`, the type of `m`:

```
fun (n0 : nat) =>
  (fun (H : n <= m) => le_plus_trans n m 1 H)
: ∀ n0, n <= m -> n <= m + 1
```

The substitution step replaces `m` with `n0`:

```
fun (n0 : nat) =>
  (fun (H : n <= n0) => le_plus_trans n n0 1 H)
: ∀ n0, n <= n0 -> n <= n0 + 1
```

Abstraction uses a list of *abstraction strategies* to determine what subterms to substitute. In this case, the simplest strategy works: The tool replaces all terms that are convertible to the concrete argument `m` with the abstract argument `n0`, which produces a single candidate. Type-checking this candidate confirms that it is a patch.

In some cases, the simplest strategy is not sufficient, even when it is possible to abstract the term. It may be possible to produce a patch only by abstracting *some* of the subterms convertible to the argument or function (we show an example of this in Section **??**), or the term may not contain any subterms convertible to the argument or function at all. We implement several strategies to account for this. The combinations strategy, for example, tries all combinations of substituting only some of the convertible subterms with the abstract argument. The pattern-based strategy substitutes subterms that match a certain pattern with a term that corresponds to that pattern.

It is the job of the patch finding procedure to provide the candidate and the terms to abstract. In addition, each configuration includes a list of strategies. The configuration for changes in conclusions, for example, starts with the simplest strategy, and moves on to more complex strategies only if that strategy fails. This design makes abstraction simple to extend with new strategies and simple to call with different strategies for different classes of changes.

PATCH INVERSION Patch inversion (`inverting.ml`) exploits symmetry to try to reverse the conclusions of a candidate patch. It first factors the candidate using the factoring component, then calls the primitive inversion function on each factor, then finally folds the resulting list in reverse. The primitive inversion function exploits symmetry. For example, equality is symmetric, so the component can invert any application of `eq_ind` or `eq_ind_r` (any rewrite). Indeed, `eq_ind` and `eq_ind_r` are inverses, and are related by symmetry:

```
eq_ind_r A x P (H : P x) y (H0 : y = x) :=
  eq_ind x (fun y0 : A => P y0) H y (eq_sym H0)
```

If inversion does not recognize that the type is symmetric, it swaps subterms and type-checks the result to see if it is an inverse.

LEMMA FACTORING The lemma factoring component (`factoring .ml`) searches within a term for its factors. For example, if the term composes two functions, it returns both factors:

```
 t : X -> Z              (* term *)
[f : X -> Y; g : Y -> Z] (* factors *)
```

In this case, the component takes the composite term and `X` as arguments. It first searches as deep as possible for a term of type `X -> Y` for some `Y`. If it finds such a term, then it recursively searches for a term with type `Y -> Z`. It maintains all possible paths of factors along the way, and it discards any paths that cannot reach `Z`.

The current implementation can handle paths with more than two factors, but it fails when `Y` depends on `X`. Other components may benefit from dependent factoring; we leave this to future work.

3.5.1.3 *Inside the Procedure*

The implementation (`patcher.ml4`) of the procedure from Section **??** starts with a preprocessing step which compiles the proof terms to trees (like the tree in Figure 3). It then searches for candidates one step at a time, expanding the trees when necessary.

The PUMPKIN prototype exposes the patch finding procedure to users through the Coq command `Patch Proof`. PUMPKIN automatically infers which configuration to use for the procedure from the example change. For example, to find a patch for the case study in Section 3.6.1, we used this command:

```
Patch Proof Old.unsigned_range unsigned_range as patch.
```

PUMPKIN analyzed both versions of `unsigned_range` and determined that a constructor of the `int` type changed (Figure 4), so it initialized the configuration for changes in constructors.

Internally, PUMPKIN represents configurations as sets of options, which it passes to the procedure. The procedure uses these options to determine how to compose components (for example, whether to abstract candidates) and how to customize components (for example, whether semantic differencing should look for an intermediate lemma). To implement new configurations for different classes of changes, we simply tweak the options.

3.5.2 *Workflow Integration*

Needed: hints and so on, any work done since, the Git interface, whatever.

3.5.2.1 *Trusted Computing Base*

A common concern for Coq plugins is an increase in the trusted computing base. The Coq developers provide a safe plugin API in Coq 8.7 to address this [34]. Our prototype takes this into consideration: While PUMPKIN does not yet support Coq 8.7, it only calls the internal Coq functions that the developers plan to expose in the safe API [50]. Furthermore, Coq type-checks terms that plugins produce. Since PUMPKIN does not modify the type checker, it cannot produce an ill-typed term.

3.6 RESULTS

Needed: key technical results

We used the PUMPKIN prototype to emulate three motivating scenarios from real-world code:

1. **Updating definitions** within a project
   (CompCert, Section 3.6.1)

```
Record int : Type :=
  mkint { intval: Z; intrange
      : 0 <= intval < modulus
       }.
```

```
Record int : Type :=
  mkint { intval: Z; intrange
      : -1 < intval < modulus
       }.
```

Figure 4: Old (left) and new (right) definitions of `int` in CompCert.

2. **Porting definitions** between libraries
   (Software Foundations, Section 3.6.2)

3. **Updating proof assistant versions**
   (Coq Standard Library, Section 3.6.3)

The code we chose for these scenarios demonstrated different classes of changes. For each case, we describe how PUMPKIN configures the procedure to use the core components for that class of changes. Our experiences with these scenarios suggest that patches are useful and that the components are effective and flexible.

IDENTIFYING CHANGES We identified Git commits from popular Coq projects that demonstrated each scenario. These commits updated proofs in response to breaking changes. We emulated each scenario as follows:

1. *Replay* an example proof update for PUMPKIN

2. *Search* the example for a patch using PUMPKIN

3. *Apply* the patch to fix a different broken proof

Our goal was to simulate incremental use of a patch finding tool, at the level of a small change or a commit that follows best practices. We favored commits with changes that we could isolate. When isolating examples for PUMPKIN, we replayed changes from the bottom up, as if we were making the changes ourselves. This means that we did not always make the same change as the user. For example, the real change from Section 3.6.1 updated multiple definitions; we updated only one.

PUMPKIN is a proof-of-concept and does not yet handle some kinds of proofs. In each scenario, we made minor modifications to proofs so that we could use PUMPKIN (for example, using induction instead of destruction). PUMPKIN does not yet handle structural changes like adding constructors or parameters, so we focused on changes that preserve structure, like modifying constructors. Chapter 4 describes an extension to PUMPKIN that supports changes in structure.

3.6.1 *Updating Definitions*

Coq programmers sometimes make changes to definitions that break proofs within the same project. To emulate this use case, we identified

```
Fixpoint bin_to_nat (b : bin) :
    nat :=
  match b with
  | B0 => 0
  | B2 b' => 2 * (bin_to_nat b
     ')
  | B21 b' => 1 + 2 * (
     bin_to_nat b')
  end.
```

```
Fixpoint bin_to_nat (b : bin) :
    nat :=
  match b with
  | B0 => 0
  | B2 b' => (bin_to_nat b') +
      (bin_to_nat b')
  | B21 b' => S ((bin_to_nat b
     ') + (bin_to_nat b'))
  end.
```

Figure 5: Definitions of bin_to_nat for Users A (left) and B (right).

a CompCert commit [53] with a breaking change to int (Figure 4). We used Pumpkin to find a patch that corresponds to the change in int. The patch Pumpkin found fixed broken inductive proofs.

REPLAY We used the proof of unsigned_range as the example for Pumpkin. The proof failed with the new int:

```
Theorem unsigned_range:
  ∀(i : int), 0 <= unsigned i < modulus.
Proof.
  intros i. induction i using int_ind; auto.X
```

We replayed the change to unsigned_range:

```
  intros i. induction i using int_ind. simpl.  omega.✓
```

SEARCH We used Pumpkin to search the example for a patch that corresponds to the change in int. It found a patch with this type:

```
 ∀ z : Z, -1 < z < modulus -> 0 <= z < modulus
```

APPLY After changing the definition of int, the proof of the theorem repr_unsigned failed on the last tactic:

```
Theorem repr_unsigned:
  ∀(i : int), repr (unsigned i) = i.
Proof.
  ... apply Zmod_small; auto.X
```

Manually trying omega—the tactic which helped us in the proof of unsigned_range—did not succeed. We added the patch that Pumpkin found to a hint database. The proof of the theorem repr_unsigned then went through:

```
  ... apply Zmod_small; auto.✓
```

3.6.1.1 *Configuration*

This scenario used the configuration for changes in constructors of an inductive type. Given such a change:

```
Inductive T := ... | C : ... -> H -> T
Inductive T' := ... | C : ... -> H' -> T'
```

Pumpkin searches two inductive proofs of theorems:

```
∀ (t : T), P t
∀ (t : T'), P t
```

for an isomorphism[4] between the constructors:

```
... -> H -> H’
... -> H’ -> H
```

The user can apply these patches within the inductive case that corresponds to the constructor `C` to fix other broken proofs that induct over the changed type. PUMPKIN uses this configuration for changes in constructors:

---

diff inductive constructors for goals
use *all components* to recursively search for changes in conclusions of the corresponding case of the proof
if there are candidates **then**
    try to *invert* the patch to find an isomorphism

3.6.2 *Porting Definitions*

Coq programmers sometimes port theorems and proofs to use definitions from different libraries. To simulate this, we used PUMPKIN to port two solutions [2, 7] to an exercise in Software Foundations to each use the other solution’s definition of the fixpoint `bin_to_nat` (Figure 5). We demonstrate one direction; the opposite was similar.

REPLAY We used the proof of `bin_to_nat_pres_incr` from User A as the example for PUMPKIN. User A cut an inline lemma in an inductive case and proved it using a rewrite:

```
assert (∀a, S (a + S (a + 0)) = S (S (a + (a + 0)))).
- ... rewrite <- plus_n_O. rewrite -> plus_comm.
```

When we ported User A’s solution to use User B’s definition of `bin_to_nat`, the application of this inline lemma failed. We changed the conclusion of the inline lemma and removed the corresponding rewrite:

```
assert (∀a, S (a + S a) = S (S (a + a))).
- ... rewrite -> plus_comm.
```

SEARCH We used PUMPKIN to search the example for a patch that corresponds to the change in `bin_to_nat`. It found an isomorphism:

```
∀P b, P (bin_to_nat b) -> P (bin_to_nat b + 0)
∀P b, P (bin_to_nat b + 0) -> P (bin_to_nat b)
```

APPLY After porting to User B’s definition, a rewrite in the proof of the theorem `normalize_correctness` failed:

```
Theorem normalize_correctness:
  ∀b, nat_to_bin (bin_to_nat b) = normalize b.
Proof.
  ... rewrite -> plus_0_r.X
```

4 If PUMPKIN finds just one implication, it returns that.

Attempting the obvious patch from the difference in tactics—rewriting by `plus_n_O`—failed. Applying the patch that PUMPKIN found fixed the broken proof:

```
... apply patch_inv. rewrite -> plus_0_r.✓
```

In this case, since we ported User A's definition to a simpler definition,[5] PUMPKIN found a patch that was not the most natural patch. The natural patch would be to remove the rewrite, just as we removed a different rewrite from the example proof. This did not occur when we ported User B's definition, which suggests that in the future, a patch finding tool may help inform novice users which definition is simpler: It can factor the proof, then inform the user if two factors are inverses. Tactic-level changes do not provide enough information to determine this; the tool must have a semantic understanding of the terms.

3.6.2.1 *Configuration*

This scenario used the configuration for changes in cases of a fixpoint. Given such a change:

```
Fixpoint f ... := ... | g x
Fixpoint f' ... := ... | g x'
```

PUMPKIN searches two proofs of theorems:

```
∀ ..., P (f ...)
∀ ..., P (f' ...)
```

for an isomorphism that corresponds to the change:

```
∀P, P x -> P x'
∀P, P x' -> P x
```

The user can apply these patches to fix other broken proofs about the fixpoint.

The key feature that differentiates these from the patches we have encountered so far is that these patches hold for *all* `P`; for changes in fixpoint cases, the procedure abstracts candidates by `P`, not by its arguments. PUMPKIN uses this configuration for changes in fixpoint cases:

---

diff fixpoint cases for goals
use *all components* to recursively search an intermediate lemma for a change in conclusions
if there are candidates **then**
    specialize and *factor* the candidate
    abstract the factors by functions
    try to *invert* the patch to find an isomorphism

For the prototype, we require the user to cut the intermediate lemma explicitly and to pass its type and arguments. In the future, an improved semantic differencing component can infer both the

5 User A uses `*`; User B uses `+`. For arbitrary `n`, the term `2 * n` reduces to `n + (n + 0)`, which does not reduce any further.

```
Definition divide p q := ∃
    r, p * r = q.
```

```
Definition divide p q := ∃
    r, q = r * p.
```

Figure 6: Old (left) and new (right) definitions of `divide` in Coq.

intermediate lemma and the arguments: It can search within the proof for some proof of a function that is applied to the fixpoint.

3.6.3 *Updating Proof Assistant Versions*

Coq sometimes makes changes to its standard library that break backwards-compatibility. To test the plausibility of using a patch finding tool for proof assistant version updates, we identified a breaking change in the Coq standard library [54]. The commit changed the definition of `divide` prior to the Coq 8.4 release (Figure 6). The change broke 46 proofs in the standard library. We used Pumpkin to find an isomorphism that corresponds to the change in `divide`. The isomorphism Pumpkin found fixed broken proofs.

REPLAY We used the proof of `mod_divide` as the example for Pumpkin. The proof broke with the new `divide`:

```
Theorem mod_divide:
  ∀ a b, b~=0 -> (a mod b == 0 <-> (divide b a)).
Proof.
  ... rewrite (div_mod a b Hb) at 2.X
```

We replayed changes to `mod_divide`:

```
  ... rewrite mul_comm.  symmetry.
  rewrite (div_mod a b Hb) at 2.✓
```

SEARCH We used Pumpkin to search the example for a patch that corresponds to the change in `divide`. It found an isomorphism:

```
∀r p q, p * r = q -> q = r * p
∀r p q, q = r * p -> p * r = q
```

APPLY The proof of the theorem `Zmod_divides` broke after rewriting by the changed theorem `mod_divide`:

```
Theorem Zmod_divides:
  ∀a b, b<>0 -> (a mod b = 0 <-> ∃c, a = b * c).
Proof.
  ... split; intros (c,Hc); exists c; auto.X
```

Adding the patches Pumpkin found to a hint database made the proof go through:

```
  ... split; intros (c,Hc); exists c; auto.✓
```

3.6.3.1 *Configuration*

This scenario used the configuration for changes in dependent arguments to constructors. PUMPKIN searches two proofs that apply the same constructor to different dependent arguments:

```
... (C (P x)) ...
... (C (P' x)) ...
```

for an isomorphism between the arguments:

```
∀ x, P x -> P' x
∀ x, P' x -> P x
```

The user can apply these patches to patch proofs that apply the constructor (in this case study, to fix broken proofs that instantiate `divide` with some specific `r`).

So far, we have encountered changes of this form as arguments to an induction principle; in this case, the change is an argument to a constructor. A patch between arguments to an induction principle maps directly between conclusions of the new and old theorem without induction; a patch between constructors does not. For example, for `divide`, we can find a patch with this form:

```
∀x, P x -> P' x
```

However, without using the induction principle for `exists`, we can't use that patch to prove this:

```
(∃x, P x) -> (∃ x, P' x)
```

This changes the goal type that semantic differencing determines. PUMPKIN uses this configuration for changes in constructor arguments:

1: *diff* constructor arguments for goals
2: use *all components* to recursively search those arguments for changes in conclusions

3: **if** there are candidates **then**
4:     *abstract* the candidate
    factor and try to *invert* the patch to find an isomorphism

---

For the prototype, the model of constructors for the semantic differencing component is limited, so we ask the user to provide the type of the change in argument (to guide line 2). We can extend semantic differencing to remove this restriction.

3.7 CONCLUSION

Rehashing thesis and how we do it

What we haven't accomplished yet at this point (parts of PUMPKIN PATCH future work), segue into next chapter

4

PROOF REPAIR ACROSS TYPE EQUIVALENCES

This extension to the suite adds support for a broad class of changes in datatypes, handling a large class of practical repair scenarios. What this tool (PUMPKIN Pi) does is, when datatypes change and this breaks a lot of proofs, it generalizes the change in datatype itself (possibly with some user input) so that it can automatically fix proofs broken by the change in datatype.

So in other words, the information from those changes is carried in the difference between the old and new version of the changed datatype, possibly with some user input.

PUMPKIN Pi generalizes that information and applies it automatically.

The work saved is shown on a lot of case studies (see Table from PUMPKIN Pi).

4.1 MOTIVATING EXAMPLE

Consider a simple example of using PUMPKIN Pi: repairing proofs after swapping the two constructors of the `list` datatype (Figure 7). This is inspired by a similar change from a user study of proof engineers (Section 4.6). Even such a simple change can cause trouble, as in this proof from the Coq standard library (comments ours for clarity):[1]

```
Lemma rev_app_distr {A} :
  ∀ (x y : list A), rev (x ++ y) = rev y ++ rev x.
```

1 We use induction instead of pattern matching.

```
Inductive list (T : Type) :
    Type :=
| nil : list T
| cons : T → list T → list
    T.
```

```
Inductive list (T : Type) :
    Type :=
| cons : T → list T → list
    T
| nil : list T.
```

Figure 7: A change from the old version of `list` (left) to the new version of `list` (right). The old version of `list` is an inductive datatype that is either empty (the `nil` constructor), or the result of placing an element in front of another `list` (the `cons` constructor). The change swaps these two constructors (orange).

```
swap T (l : Old.list T) : New.
    list T :=
  Old.list_rect T (fun (l :
      Old.list T) => New.list T
      )
    New.nil
    (fun t _ (IHl : New.list T)
        => New.cons T t IHl)
    l.
```

```
swap⁻¹ T (l : New.list T) :
    Old.list T :=
  New.list_rect T (fun (l :
      New.list T) => Old.list T
      )
    (fun t _ (IHl : Old.list T)
        => Old.cons T t IHl)
    Old.nil
    l.
```

```
Lemma section: ∀ T (l : Old.
    list T),
  swap⁻¹ T (swap T l) = l.
Proof.
  intros T l. symmetry.
      induction l as [ |a l0 H
      ].
  - auto.
  - simpl. rewrite ← H. auto.
Qed.
```

```
Lemma retraction: ∀ T (l : New.
    list T),
  swap T (swap⁻¹ T l) = l.
Proof.
  intros T l. symmetry.
      induction l as [t l0 H|
      ].
  - simpl. rewrite ← H. auto.
  - auto.
Qed.
```

Figure 8: Two functions between `Old.list` and `New.list` (top) that form an equivalence (bottom).

```
Proof. (* by induction over x and y *)
  induction x as [| a l IHl].
  (* x nil:  *) induction y as [| a l IHl].
  (* y nil:  *) simpl. auto.
  (* y cons *) simpl. rewrite app_nil_r; auto.
  (* both cons:  *) intro y. simpl.
  rewrite (IHl y). rewrite app_assoc; trivial.
Qed.
```

This lemma says that appending (++) two lists and reversing (`rev`) the result behaves the same as appending the reverse of the second list onto the reverse of the first list. The proof script works by induction over the input lists `x` and `y`: In the base case for both `x` and `y`, the result holds by reflexivity. In the base case for `x` and the inductive case for `y`, the result follows from the existing lemma `app_nil_r`. Finally, in the inductive case for both `x` and `y`, the result follows by the inductive hypothesis and the existing lemma `app_assoc`.

When we change the `list` type, this proof no longer works. To repair this proof with Pumpkin Pi, we run this command:

```
Repair Old.list New.list in rev_app_distr.
```

assuming the old and new list types from Figure 7 are in modules `Old` and `New`. This suggests a proof script that succeeds (in light blue to denote Pumpkin Pi produces it automatically):

```
Proof. (* by induction over x and y *)
  intros x. induction x as [a l IHl| ]; intro y0.
  - (* both cons:  *) simpl. rewrite IHl. simpl.
    rewrite app_assoc. auto.
  - (* x nil:  *) induction y0 as [a l H| ].
    + (* y cons:  *) simpl. rewrite app_nil_r. auto.
    + (* y nil:  *) auto.
Qed.
```

where the dependencies (`rev`, `++`, `app_assoc`, and `app_nil_r`) have also been updated automatically ①. If we would like, we can manually modify this to something that more closely matches the style of the original proof script:

```
Proof. (* by induction over x and y *)
  induction x as [a l IHl|].
  (* both cons:  *) intro y. simpl.
  rewrite (IHl y). rewrite app_assoc; trivial.
  (* x nil:  *) induction y as [a l IHl|].
  (* y cons:  *) simpl. rewrite app_nil_r; auto.
  (* y nil:  *) simpl. auto.
Qed.
```

We can even repair the entire list module from the Coq standard library all at once by running the `Repair module` command ①. When we are done, we can get rid of `Old.list`.

The key to success is taking advantage of Coq's structured proof term language: Coq compiles every proof script to a proof term in a rich functional programming language called Gallina—PUMPKIN Pi repairs that term. PUMPKIN Pi then decompiles the repaired proof term (with optional hints from the original proof script) back to a suggested proof script that the proof engineer can maintain.

In contrast, updating the poorly structured proof script directly would not be straightforward. Even for the simple proof script above, grouping tactics by line, there are $6! = 720$ permutations of this proof script. It is not clear which lines to swap since these tactics do not have a semantics beyond the searches their evaluation performs. Furthermore, just swapping lines is not enough: even for such a simple change, we must also swap arguments, so `induction x as [| a l IHl ]` becomes `induction x as [a l IHl|]`. A recent thesis [79] describes the challenges of repairing tactics in detail. PUMPKIN Pi's approach circumvents this challenge.

4.2 APPROACH

PUMPKIN Pi can do much more than permute constructors. Given an equivalence between types A and B, PUMPKIN Pi repairs functions and proofs defined over A to instead refer to B. It does this in a way that allows for removing references to A, which is essential for proof repair, since A may be an old version of an updated type.

Like I mentioned earlier, this also works using differencing and program transformations over proof terms. Here, differencing thus looks at the difference between versions of the changed datatype, and finds something called a type equivalence (Section 4.2.1). Sometimes differencing is automatic, and sometimes it's manual. Then, program transformation ports proofs across the equivalence directly (Section 4.2.2). So they take care of application.

Figure 9 shows how this comes together when the proof engineer invokes PUMPKIN Pi:

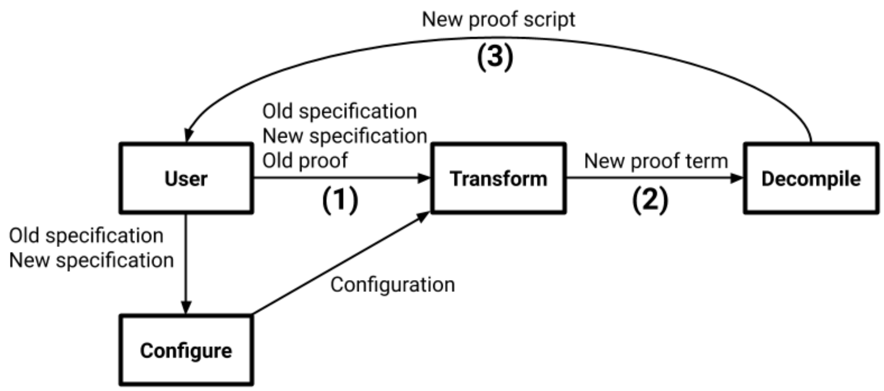

Figure 9: The workflow for Pumpkin Pi.

1. The proof engineer **Configure**s Pumpkin Pi, either manually or automatically.
2. The configured **Transform** transforms the old proof term into the new proof term.
3. **Decompile** suggests a new proof script.

There are currently four search procedures for automatic configuration implemented in Pumpkin Pi (see Table 1 on page 55). Manual configuration makes it possible for the proof engineer to configure the transformation to any equivalence, even without a search procedure. Section 4.6 shows examples of both workflows applied to real scenarios

4.2.1 *Scope: Type Equivalences*

Pumpkin Pi repairs proofs in response to changes in types that correspond to *type equivalences* [85], or pairs of functions that map between two types and are mutual inverses.[2] When a type equivalence between types A and B exists, those types are *equivalent* (denoted $A \simeq B$). Figure 8 shows a type equivalence between the two versions of `list` from Figure 7 that Pumpkin Pi discovered and proved automatically (1).

To give some intuition for what kinds of changes can be described by equivalences, we preview two changes below. See Table 1 on page 55 for more examples.

Factoring out Constructors. Consider changing the type `I` to the type `J` in Figure 10. `J` can be viewed as `I` with its two constructors `A` and `B` pulled out to a new argument of type `bool` for a single constructor. With Pumpkin Pi, the proof engineer can repair functions and proofs about `I` to instead use `J`, as long as she configures Pumpkin Pi to describe which constructor of `I` maps to `true` and which maps to `false`. This information about constructor mappings induces an equivalence

2 The adjoint follows, and Pumpkin Pi includes machinery to prove it (10) (23).

`I` $\simeq$ `J` across which Pumpkin Pi repairs functions and proofs. File ② shows an example of this, mapping `A` to `true` and `B` to false, and repairing proofs of De Morgan's laws.

Adding a Dependent Index. At first glance, the word *equivalence* may seem to imply that Pumpkin Pi can support only changes in which the proof engineer does not add or remove information. But equivalences are more powerful than they may seem. Consider, for example, changing a list to a length-indexed vector (Figure 11). Pumpkin Pi can repair functions and proofs about lists to functions and proofs about vectors of particular lengths ③, since Σ`(l:list T).length l = n` $\simeq$ `vector T n`. From the proof engineer's perspective, after updating specifications from `list` to `vector`, to fix her functions and proofs, she must additionally prove invariants about the lengths of her lists. Pumpkin Pi makes it easy to separate out that proof obligation, then automates the rest.

More generally, in homotopy type theory, with the help of quotient types, it is possible to form an equivalence from a relation, even when the relation is not an equivalence [3]. While Coq lacks quotient types, it is possible to achieve a similar outcome and use Pumpkin Pi for changes that add or remove information when those changes can be expressed as equivalences between Σ types or sum types.

4.2.2 *Goal: Transport with a Twist*

The goal of Pumpkin Pi is to implement a kind of proof reuse known as *transport* [85], but in a way that is suitable for repair. Informally, transport takes a term t and produces a term t' that is the same as t modulo an equivalence $A \simeq B$. If t is a function, then t' behaves the same way modulo the equivalence; if t is a proof, then t' proves the same theorem the same way modulo the equivalence.

When transport across $A \simeq B$ takes t to t', we say that t and t' are *equal up to transport* across that equivalence (denoted $t \equiv_{A \simeq B} t'$).[3] In Section 4.1, the original append function ++ over `Old.list` and the repaired append function ++ over `New.list` that Pumpkin Pi produces are equal up to transport across the equivalence from Figure 8, since (by `app_ok` ①):

```
∀ T (l1 l2 : Old.list T),
  swap T (l1 ++ l2) = (swap T l1) ++ (swap T l2).
```

The original `rev_app_distr` is equal to the repaired proof up to transport, since both prove the same thing the same way up to the equivalence, and up to the changes in ++ and `rev`.

3 This notation should be interpreted in a metatheory with *univalence*—a property that Coq lacks—or it should be approximated in Coq. The details of transport with univalence are in the Homotopy Type Theory book [85], and an approximation in Coq is in the univalent parametricity framework paper [82]. For equivalent A and B, there can be many equivalences $A \simeq B$. Equality up to transport is across a *particular* equivalence, but we erase this in the notation.

```
Inductive I :=
| A : I
| B : I.
```

```
Inductive J :=
| makeJ : bool → J.
```

Figure 10: The old type I (left) is either A or B. The new type J (right) is I with A and B factored out to bool (orange).

```
Inductive list (T : Type) :
    Type :=
| nil : list T
| cons : T → list T → list T.
```

```
Inductive vector (T : Type) : nat →
    Type :=
| nil : vector T O
| cons : T → ∀ (n : nat), vector T
    n → vector T (S n).
```

Figure 11: A vector (bottom) is a list (top) indexed by its length (orange). Vectors effectively make it possible to enforce length invariants about lists at compile time.

Transport typically works by applying the functions that make up the equivalence to convert inputs and outputs between types. This approach would not be suitable for repair, since it does not make it possible to remove the old type A. Pumpkin Pi implements transport in a way that allows for removing references to A—by proof term transformation.

4.3 DIFFERENCING

At the heart of Pumpkin Pi is a configurable proof term transformation for transporting proofs across equivalences (4). It is a generalization of the transformation from an earlier version of Pumpkin Pi called Devoid [78], which solved this problem a particular class of equivalences.

The transformation takes as input a deconstructed equivalence that we call a *configuration*. This section introduces the configuration (Section 4.3.1), defines the transformation that builds on that (Section **??**), then specifies correctness criteria for the configuration (Section 4.3.2). Section **??** describes the additional work needed to implement this transformation.

Conventions. All terms that we introduce in this section are in the Calculus of Inductive Constructions (CIC_ω), the type theory that

$$\langle i \rangle \in \mathbb{N},\ \ \langle v \rangle \in \text{Vars},\ \langle s \rangle \in \{\ \text{Prop, Set, Type}\langle i \rangle\ \}$$

$$\langle t \rangle ::= \ \langle v \rangle \ \mid\ \langle s \rangle \ \mid\ \Pi\,(\langle v \rangle : \langle t \rangle)\ .\ \langle t \rangle \ \mid\ \lambda\,(\langle v \rangle : \langle t \rangle)\ .\ \langle t \rangle \ \mid\ \langle t \rangle\ \langle t \rangle \ \mid\ \text{Ind}\ (\langle v \rangle : \langle t \rangle)\{\langle t \rangle,\ldots,\langle t \rangle\} \ \mid\ \text{Constr}\ (\langle i \rangle,\ \langle t \rangle) \ \mid\ \text{Elim}(\langle t \rangle,\ \langle t \rangle)\{\langle t \rangle,\ldots,\langle t \rangle\}$$

Figure 12: Syntax for CIC_ω from an existing paper [84] with (from left to right) variables, sorts, dependent types, functions, application, inductive types, inductive constructors, and primitive eliminators.

```
DepConstr(0, list T) : list T

     P l :=
  Elim(l, P) { pcons, pnil }.
```

Figure 13: The dependent constructors and eliminators for old (left) and new (right) `list`, with the difference in orange.

Coq's proof term language Gallina implements. CIC$_\omega$ is based on the Calculus of Constructions (CoC), a variant of the lambda calculus with polymorphism (types that depend on types) and dependent types (types that depend on terms) [23]. CIC$_\omega$ extends CoC with inductive types [24]. Inductive types are defined solely by their constructors (like `nil` and `cons` for `list`) and eliminators (like the induction principle for `list`); this section assumes that these eliminators are primitive.

The syntax for CIC$_\omega$ with primitive eliminators is in Figure 16. The typing rules are standard. We assume inductive types Σ with constructor $\exists$ and projections π_l and π_r, and an equality type = with constructor `eq_refl`. We use $\vec{t}$ and $\{t_1, \ldots, t_n\}$ to denote lists of terms.

4.3.1 *The Configuration*

The configuration is the key to building a proof term transformation that implements transport in a way that is suitable for repair. Each configuration corresponds to an equivalence $A \simeq B$. It deconstructs the equivalence into things that talk about A, and things that talk about B. It does so in a way that hides details specific to the equivalence, like the order or number of arguments to an induction principle or type.

At a high level, the configuration helps the transformation achieve two goals: preserve equality up to transport across the equivalence between A and B, and produce well-typed terms. This configuration is a pair of pairs:

```
((DepConstr, DepElim), (Eta, Iota))
```

each of which corresponds to one of the two goals: `DepConstr` and `DepElim` define how to transform constructors and eliminators, thereby preserving the equivalence, and `Eta` and `Iota` define how to transform η-expansion and ι-reduction of constructors and eliminators, thereby producing well-typed terms. Each of these is defined in CIC$_\omega$ for each equivalence.

Carlo theory will go here: basically the names aren't coincidences, it's because this corresponds to an initial algebra, so it's more natural when you have inductive types but more general than that. Draw diagram, explain what each part corresponds to.

Preserving the Equivalence. To preserve the equivalence, the configuration ports terms over A to terms over B by viewing each term of type B as if it were an A. This way, the rest of the transformation can replace values of A with values of B, and inductive proofs about A with inductive proofs about B, all without changing the order or number of arguments.

The two configuration parts responsible for this are `DepConstr` and `DepElim` (*dependent constructors* and *eliminators*). These describe how to construct and eliminate A and B, wrapping the types with a common inductive structure. The transformation requires the same number of dependent constructors and cases in dependent eliminators for A and B, even if A and B are types with different numbers of constructors (A and B need not even be inductive; see Sections 4.3.2 and 4.6).

For the `list` change from Section 4.1, the configuration that Pumpkin Pi discovers uses the dependent constructors and eliminators in Figure 13. The dependent constructors for `Old.list` are the normal constructors with the order unchanged, while the dependent constructors for `New.list` swap constructors back to the original order. Similarly, the dependent eliminator for `Old.list` is the normal eliminator for `Old.list`, while the dependent eliminator for `New.list` swaps cases.

As the name hints, these constructors and eliminators can be dependent. Consider the type of vectors of some length:

```
packed_vect T := Σ(n : nat).vector T n.
```

Pumpkin Pi can port proofs across the equivalence between this type and `list T` 3. The dependent constructors Pumpkin Pi discovers pack the index into an existential, like:

```
DepConstr(0, packed_vect) : packed_vect T :=
  ∃ (Constr(0, nat)) (Constr(0, vector T)).
```

and the eliminator it discovers eliminates the projections:

```
DepElim(s, P) { f₀ f₁ } : P (∃ (π_l s) (π_r s)) :=
  Elim(π_r s, λ(n : nat)(v : vector T n).P (∃ n v)) {
    f₀,
    (λ(t : T)(n : nat)(v : vector T n).f₁ t (∃ n v))
  }.
```

In both these examples, the interesting work moves into the configuration: the configuration for the first swaps constructors and cases, and the configuration for the second maps constructors and cases over `list` to constructors and cases over `packed_vect`. That way, the transformation need not add, drop, or reorder arguments. Furthermore, both examples use automatic configuration, so Pumpkin Pi's **Configure** component discovers `DepConstr` and `DepElim` from just the types A and B, taking care of even the difficult work.

Producing Well-Typed Terms. The other configuration parts `Eta` and `Iota` deal with producing well-typed terms, in particular by transporting equalities. CIC_ω distinguishes between two important kinds of equality: those that hold by reduction (*definitional* equality), and those

```
Inductive positive :=
| xI : positive → positive
| xO : positive → positive
| xH : positive.
```

```
Inductive nat :=
| O : nat
| S : nat → nat.
```

```
Inductive N :=
| N0 : N
| Npos : positive → N.
```

Figure 14: A unary natural number `nat` (left) is either zero (`O`) or the successor of some other natural number (`S`). A binary natural number `N` (right) is either zero (`N0`) or a positive binary number (`Npos`), where a positive binary number is either 1 (`xH`), or the result of shifting left and adding 1 (`xI`) or 0 (`xO`). Unary and binary natural numbers are equivalent, but have different inductive structures. Consequentially, definitional equalities over `nat` may become propositional over `N`.

that hold by proof (*propositional* equality). That is, two terms `t` and `t'` of type `T` are definitionally equal if they reduce to the same normal form, and propositionally equal if there is a proof that `t = t'` using the inductive equality type `=` at type `T`. Definitionally equal terms are necessarily propositionally equal, but the converse is not in general true.

When a datatype changes, sometimes, definitional equalities defined over the old version of that type must become propositional. A naive proof term transformation may fail to generate well-typed terms if it does not account for this. Otherwise, if the transformation transforms a term `t : T` to some `t' : T'`, it does not necessarily transform `T` to `T'` [83].

`Eta` and `Iota` describe how to transport equalities. More formally, they define η-expansion and ι-reduction of A and B, which may be propositional rather than definitional, and so must be explicit in the transformation. η-expansion describes how to expand a term to apply a constructor to an eliminator in a way that preserves propositional equality, and is important for defining dependent eliminators [70]. ι-reduction (β-reduction for inductive types) describes how to reduce an elimination of a constructor [69].

The configuration for the change from `list` to `packed_vect` has propositional `Eta`. It uses η-expansion for Σ:

`Eta(packed_vect) :=` λ`(s:packed_vect).`$\exists$ `(`π_l `s) (`π_r `s).`

which is propositional and not definitional in Coq. Thanks to this, we can forego the assumption that our language has primitive projections (definitional η for Σ).

Each `Iota`—one per constructor—describes and proves the ι-reduction behavior of `DepElim` on the corresponding case. This is needed, for example, to port proofs about unary numbers `nat` to proofs about binary numbers `N` (Figure 14). While we can define `DepConstr` and

`DepElim` to induce an equivalence between them ⑤, we run into trouble reasoning about applications of `DepElim`, since proofs about `nat` that hold by reflexivity do not necessarily hold by reflexivity over `N`. For example, in Coq, while `S (n + m) = S n + m` holds by reflexivity over `nat`, when we define `+` with `DepElim` over `N`, the corresponding theorem over `N` does not hold by reflexivity.

To transform proofs about `nat` to proofs about `N`, we must transform *definitional* ι-reduction over `nat` to *propositional* ι-reduction over `N`. For our choice of `DepConstr` and `DepElim`, ι-reduction is definitional over `nat`, since a proof of:

```
∀ P p0 pS n,
  DepElim(DepConstr(1, nat) n, P) { p0, pS } =
  pS n (DepElim(n, P) { p0, pS }).
```

holds by reflexivity. `Iota` for `nat` in the `S` case is a rewrite by that proof by reflexivity ⑤, with type:

```
∀ P p0 pS n (Q: P (DepConstr(1, nat) n) → s),
  Iota(1, nat, Q) :
    Q (pS n (DepElim(n, P) { p0, pS })) →
    Q (DepElim(DepConstr(1, nat) n, P) { p0, pS }).
```

In contrast, ι for `N` is propositional, since the theorem:

```
∀ P p0 pS n,
  DepElim(DepConstr(1, N) n, P) { p0, pS } =
  pS n (DepElim(n, P) { p0, pS }).
```

no longer holds by reflexivity. `Iota` for `N` is a rewrite by the propositional equality that proves this theorem ⑤, with type:

```
∀ P p0 pS n (Q: P (DepConstr(1, N) n) → s),
  Iota(1, N, Q) :
    Q (pS n (DepElim(n, P) { p0, pS })) →
    Q (DepElim(DepConstr(1, N) n, P) { p0, pS }).
```

By replacing `Iota` over `nat` with `Iota` over `N`, the transformation replaces rewrites by reflexivity over `nat` to rewrites by propositional equalities over `N`. That way, `DepElim` behaves the same over `nat` and `N`.

Taken together over both A and B, `Iota` describes how the inductive structures of A and B differ. The transformation requires that `DepElim` over A and over B have the same structure as each other, so if A and B *themselves* have the same inductive structure (if they are *ornaments* [59]), then if ι is definitional for A, it will be possible to choose `DepElim` with definitional ι for B. Otherwise, if A and B (like `nat` and `N`) have different inductive structures, then definitional ι over one would become propositional ι over the other.

4.3.2 *Specifying Correct Configurations*

Choosing a configuration necessarily depends in some way on the proof engineer's intentions: there can be infinitely many equivalences that correspond to a change, only some of which are useful (for example ⑦, any A is equivalent to `unit` refined by A). And there can be many configurations that correspond to an equivalence, some of

```
section: ∀ (a : A), g (f a)
     = a.
retraction: ∀ (b : B), f (g
     b) = b.

constr_ok: ∀ j x⃗_A x⃗_B, x⃗_A
     ≡_{A≃B} x⃗_B →
  DepConstr(j, A) x⃗_A ≡_{A≃B}
      DepConstr(j, B) x⃗_B.

elim_ok: ∀ a b P_A P_B f⃗_A f⃗_B,
  a ≡_{A≃B} b →
  P_A ≡_{(A→s)≃(B→s)} P_B →
  ∀ j, f⃗_A[j] ≡_{ξ(A,P_A,j)≃ξ(B,P_B,j)}
       f⃗_B[j]→
  DepElim(a, P_A) f⃗_A
      ≡_{(Pa)≃(Pb)} DepElim(b, P
      _B) f⃗_A.
```

```
elim_eta(A): ∀ a P f⃗, DepElim(a, P)
     f⃗ : P (Eta(A) a).
eta_ok(A): ∀ (a : A), Eta(A) a = a.

iota_ok(A): ∀ j P f⃗ x⃗ (Q: P(Eta(A)
     (DepConstr(j, A) x⃗)) → s),
  Iota(A, j, Q) :
    Q (DepElim(DepConstr(j, A) x⃗, P)
         f⃗) →
    Q (rew ← eta_ok(A) (DepConstr(j
        , A) x⃗) in
      (f⃗[j]...(DepElim(IH_0, P) f⃗)...(
          DepElim(IH_n, P) f⃗)...)).
```

Figure 15: Correctness criteria for a configuration to ensure that the transformation preserves equivalence (left) coherently with equality (right, shown for A; B is similar). `f` and `g` are defined in text. s, $\vec{f}$, $\vec{x}$, and $\vec{\text{IH}}$ represent sorts, eliminator cases, constructor arguments, and inductive hypotheses. ξ (A, P, j) is the type of `DepElim(A, P)` at `DepConstr(j, A)` (similarly for B).

which will produce terms that are more useful or efficient than others (consider `DepElim` converting through several intermediate types).

While we cannot control for intentions, we *can* specify what it means for a chosen configuration to be correct: Fix a configuration. Let `f` be the function that uses `DepElim` to eliminate A and `DepConstr` to construct B, and let `g` be similar. Figure 15 specifies the correctness criteria for the configuration. These criteria relate `DepConstr`, `DepElim`, `Eta`, and `Iota` in a way that preserves equivalence coherently with equality.

Equivalence. To preserve the equivalence (Figure 15, left), `DepConstr` and `DepElim` must form an equivalence (`section` and `retraction` must hold for `f` and `g`). `DepConstr` over A and B must be equal up to transport across that equivalence (`constr_ok`), and similarly for `DepElim` (`elim_ok`). Intuitively, `constr_ok` and `elim_ok` guarantee that the transformation correctly transports dependent constructors and dependent eliminators, as doing so will preserve equality up to transport for those subterms. This makes it possible for the transformation to avoid applying `f` and `g`, instead porting terms from A directly to B.

Equality. To ensure coherence with equality (Figure 15, right), `Eta` and `Iota` must prove η and ι. That is, `Eta` must have the same definitional behavior as the dependent eliminator (`elim_eta`), and must behave like identity (`eta_ok`). Each `Iota` must prove and rewrite along the simplification (*refolding* [11]) behavior that corresponds to a case of the dependent eliminator (`iota_ok`). This makes it possible for the transformation to avoid applying `section` and `retraction`.

Correctness. With these correctness criteria for a configuration, we get the completeness result (proven in Coq ⑧) that every equivalence induces a configuration. We also obtain an algorithm for the soundness result that every configuration induces an equivalence.

The algorithm to prove `section` is as follows (`retraction` is similar): replace `a` with `Eta(A) a` by `eta_ok(A)`. Then, induct using `DepElim` over A. For each case i, the proof obligation is to show that `g (f a)` is equal to `a`, where `a` is `DepConstr(A, i)` applied to the non-inductive arguments (by `elim_eta(A)`). Expand the right-hand side using `Iota(A, i)`, then expand it again using `Iota(B, i)` (destructing over each `eta_ok` to apply the corresponding `Iota`). The result follows by definition of `g` and `f`, and by reflexivity.

4.3.3 *Search Procedures*

Pumpkin Pi implements four search procedures for automatic configuration ⑥. Three of the four procedures are based on the search procedure from Devoid [78], while the remaining procedure instantiates the types A and B of a generic configuration that can be defined inside of Coq directly.

The algorithm above is essentially what **Configure** uses to generate functions `f` and `g` for the automatic configurations ⑨, and also generate proofs `section` and `retraction` that these functions form an equivalence ⑩. To minimize dependencies, Pumpkin Pi does not produce proofs of `constr_ok` and `elim_ok` directly, as stating these theorems cleanly would require either a special framework [82] or a univalent type theory [85]. If the proof engineer wishes, it is possible to prove these in individual cases ⑧, but this is not necessary in order to use Pumpkin Pi.

4.3.3.1 *Algebraic Ornaments*

Differencing in Devoid discovers equivalences that correspond to *algebraic ornaments*. An algebraic ornament relates an inductive type A to an indexed version of that type B with a new index of type I_B, where the new index is fully determined by a unique fold over A. For example, `vector` is exactly `list` with a new index of type `nat`, where the new index is fully determined by the `length` function. Consequentially, there are two functions:

```
ltv : list T                 → Σ(n : nat).vector T n.
vtl : Σ(n : nat).vector T n → list T.
```

that are mutual inverses:

```
∀ (l : list T),              vtl (ltv l) = l.
```

$\forall$ `(v : Σ(n : nat).vector T n), ltv (vtl v) = v.`

and therefore form the type equivalence from Section **??**. Moreover, since the new index is fully determined by `length`, we can relate `length` to `ltv`:

$\forall$ `(l : list T), length l =` π_l `(ltv l).`

In general, we can view an algebraic ornament as a type equivalence:

$$A\ \vec{i}\ \simeq\ \Sigma(n : I_B\ \vec{i}).B\ (\texttt{index}\ n\ \vec{i})$$

where $\vec{i}$ are the indices of A, I_B is a function over those indices, and the `index` operation inserts the new index n at the right offset. Such a type equivalence consists of two functions [85]:

$$\texttt{promote} : A\ \vec{i} \rightarrow \Sigma(n : I_B\ \vec{i}).B\ (\texttt{index}\ n\ \vec{i}).$$
$$\texttt{forget} : \Sigma(n : I_B\ \vec{i}).B\ (\texttt{index}\ n\ \vec{i}) \rightarrow A\ \vec{i}.$$

that are mutual inverses:[4]

$$\texttt{section} : \forall\ (a : A\ \vec{i}),\ \texttt{forget}\ (\texttt{promote}\ a) = a.$$
$$\texttt{retraction} : \forall\ (b_\Sigma : \Sigma(n : I_B\ \vec{i}).B\ (\texttt{index}\ n\ \vec{i})),\ \texttt{promote}\ (\texttt{forget}\ b_\Sigma) = b_\Sigma.$$

An algebraic ornament is additionally equipped with an indexer, which is a unique fold:

$$\texttt{indexer} : A\ \vec{i} \rightarrow I_B\ \vec{i}.$$

which projects the promoted index:

$$\texttt{coherence} : \forall(a : A\ \vec{i}),\ \texttt{indexer}\ a = \pi_l\ (\texttt{promote}\ a).$$

Following existing work [49], we call this equivalence the *ornamental promotion isomorphism*; when it holds and the indexer exists, we say that B is an algebraic ornament of A.

`Find ornament` searches for algebraic ornaments between types and is, to the best of our knowledge, the first search algorithm for ornaments.

In their original form, ornaments are a programming mechanism: Given a type A, an ornament determines some new type B. We invert this process for algebraic ornaments: Given types A and B, Devoid searches for an ornament between them. This is possible for algebraic ornaments precisely because the indexer is extensionally unique. For example, all possible indexers for `list` and `vector` must compute the length of a list; if we were to try doubling the length instead, we would not be able to satisfy the equivalence.

`Find ornament` takes two inductive types and searches for the components of the ornamental promotion isomorphism between them:

- **Inputs**: Inductive types A and B, assuming:
  - B is an algebraic ornament of A,
  - B has the same number of constructors in the same order as A,

4 The adjunction condition follows from section and retraction.

  - A and B do not contain recursive references to themselves under products, and
  - for every recursive reference to A in A, there is exactly one new hypothesis in B, which is exactly the new index of the corresponding recursive reference in B.
- **Outputs**: Functions `promote`, `forget`, and `indexer`, guaranteeing:
  - the outputs form the ornamental promotion isomorphism between the inputs.

`Find ornament` includes an option to generate a proof that the outputs form the ornamental promotion isomorphism; by default, this option is false, since `Lift` does not need this proof.

Presentation. We present both algorithms relationally, using a set of judgments; to turn these relations into algorithms, prioritize the rules by running the derivations in order, falling back to the original term when no rules match. The default rule for a list of terms is to run the derivation on each element of the list individually.

Notes on Syntax. The language the algorithms operate over is CIC_ω with primitive eliminators; this is a simplified version of the type theory underlying Coq. Figure 16 contains the syntax (which includes variables, sorts, product types, functions, inductive types, constructors, and eliminators), as well as the syntax for some judgments and operations, the rules for which are standard and thus omitted. For simplicity of presentation, we assume variables are names; we assume that all names are fresh. As in Coq, we assume the existence of an inductive type Σ for sigma types with projections π_l and π_r; for simplicity, we assume projections are primitive. Throughout, we use $\vec{t}$ and $\{t_1, \ldots, t_n\}$ to denote lists of terms, and we use $\vec{t}[j]$ to denote accessing the element of the list $\vec{t}$ at offset j.

Common Definitions. The algorithms assume list insertion and removal functions `insert` and `remove`, plus two functions Devoid implements: `off` computes the offset of the new index of type I_B in B's indices, and `new` determines whether a hypothesis in a case of the eliminator type of B is new. Figure 17 contains other common definitions, the names for which are reserved: The `index` and `deindex` functions insert an index into and remove an index from a list at the index computed by `off`. Input type A expands to an inductive type with indices of types $\vec{X_A}$, sort s_A, and constructors $\{\text{C}_{A_1}, \ldots, \text{C}_{A_n}\}$. P_A denotes the type of the motive of the eliminator of A, and each E_{A_i} denotes the type of the eliminator for the ith constructor of A. Analogous names are also reserved for input type B.

The `Find ornament` algorithm implements the specification. It builds on three intermediate steps: one to generate each of `indexer`, `promote`,

$\langle i \rangle \in \mathbb{N}$, $\langle v \rangle \in$ Vars, $\langle s \rangle \in$ { Prop, Set, Type$\langle i \rangle$ }	$\Gamma \vdash t : T$ `// type checking`

Figure 18: Identifying the indexer function.

and `forget`. Figure 18 shows the algorithm for generating `indexer`. The algorithms for generating `promote` and `forget` are similar; Figure 19 shows only the derivations for generating `promote` that are different from those for generating `indexer`, and the derivations for generating `forget` are omitted.

SEARCHING FOR THE INDEXER Search generates the `indexer` by traversing the types of the eliminators for A and B in parallel using the algorithm from Figure 18, which consists of three judgments: one to generate the motive, one to generate each case, and one to compose the motive and cases.

Generating the Motive. The $(T_A, T_B) \Downarrow_{i_m} t$ judgment consists of only the derivation INDEX-MOTIVE, which computes the indexer motive from the types A and B (expanded in Figure 17). It does this by constructing a function with A and its indices as premises, and the type I_B in the conclusion with the appropriate indices. Consider `list` and `vector`:

```
list T := Ind (TyA : Type) {...}      vector T := Ind (TyB : Π
    (n :  nat).Type) {...}
```

For these types, INDEX-MOTIVE computes the motive:

```
λ (l:list T) . nat
```

Generating Each Case. The $\Gamma \vdash (T_A, T_B) \Downarrow_{i_c} t$ judgment generates each case of the indexer by traversing in parallel the corresponding cases of the eliminator types for A and B. It consists of four derivations: INDEX-CONCLUSION handles base cases and conclusions of inductive cases, while INDEX-HYPOTHESIS, INDEX-IH, and INDEX-PROD recurse into products.

INDEX-HYPOTHESIS handles each new hypothesis that corresponds to a new index in an inductive hypothesis of an inductive case of the eliminator type for B. It adds the new index to the environment, then recurses into the body of only the type for which the index already exists. For example, in the inductive case of `list` and `vector`, `new` determines that `n` is the new hypothesis. INDEX-HYPOTHESIS then recurses into the body of only the `vector` case:

```
Π (tl:T) (l:list T) (IHl:pA l), ...     Π (tv:T) (v:vector T n)
    (IHv:pB n v), ...
```

INDEX-PROD is next. It recurses into product types when the hypothesis is neither a new index nor an inductive hypothesis. Here, it runs twice, recursing into the body and substituting names until it hits the inductive hypothesis for both types:

```
Π (IHl:pA l), pA (cons tl l)            Π (IHv:pB n l), pB
    (S n) (consV n tl l)
```

INDEX-IH then takes over. It substitutes the new motive in the inductive hypothesis, then recurses into both bodies, substituting the new inductive hypothesis for the index in the eliminator type for B. Here, it substitutes the new motive for p_A in the type of $\texttt{IH}_l$, extends the environment with $\texttt{IH}_l$, then substitutes $\texttt{IH}_l$ for `n`, so that it recurses on these types:

```
pA (cons tl l)                         pB (S IHl) (consV IHl tl l)
```

Finally, INDEX-CONCLUSION computes the conclusion by taking the index of motive p_B at off A B, here $\texttt{S IH}_l$. In total, this produces a function that computes the length of `cons t l`:

```
λ (tl:T) (l:list T) (IHl:(λ (l:list T).nat) l).S IHl
```

$$\boxed{\Gamma \vdash (T_A,\ T_B) \Downarrow_{p_m} t}$$

PROMOTE-MOTIVE
$$\frac{\Gamma \vdash (A,\ B) \Downarrow_i \pi}{\Gamma \vdash (A,\ B) \Downarrow_{p_m} \lambda(\vec{i_a} : \vec{X_A})(a : A\ \vec{i_a}).B\ (\text{index}\ (\pi\ \vec{i_a}\ a)\ \vec{i_a})}$$

$$\boxed{\Gamma \vdash (T_A,\ T_B) \Downarrow_{p_c} t}$$

PROMOTE-CONCLUSION
$$\frac{}{\Gamma \vdash (p_A\ \vec{i_A}\ a,\ p_B\ \vec{i_B}\ b) \Downarrow_{p_c} b}$$

PROMOTE-IH
$$\frac{\Gamma \vdash (A,\ B) \Downarrow_i \pi \qquad \Gamma \vdash (A,\ B) \Downarrow_{p_m} p \qquad \Gamma,\ n_A : p\ \vec{i_A}\ a \vdash (b_A,\ b_B[n_A/b][\pi\ \vec{i_A}\ a/\vec{i_B}[\text{off}\ A\ B]]) \Downarrow_{p_c} t}{\Gamma \vdash (\Pi(n_A : p_A\ \vec{i_A}\ a).b_A,\ \Pi(n_B : p_B\ \vec{i_B}\ b).b_B) \Downarrow_{p_c} \lambda(n_A : p\ \vec{i_A}\ a).t}$$

$$\boxed{\Gamma \vdash (T_A,\ T_B) \Downarrow_p t}$$

PROMOTE-IND
$$\frac{\Gamma \vdash (A,\ B) \Downarrow_i \pi \qquad \Gamma \vdash (A,\ B) \Downarrow_{p_m} p \qquad \Gamma,\ p_A : \mathrm{P}_A,\ p_B : \mathrm{P}_B \vdash \{(\mathrm{E}_{A_1}\ p_A,\ \mathrm{E}_{B_1}\ p_B), \ldots, (\mathrm{E}_{A_n}\ p_A,\ \mathrm{E}_{B_n}\ p_B)\} \Downarrow_{p_c} \vec{f}}{\Gamma \vdash (A,\ B) \Downarrow_p \lambda(\vec{i_A} : \vec{X_A})(a : A\ \vec{i_A}).\exists\ (\pi\ \vec{i_A}\ a)\ (\text{Elim}(a, p)\vec{f})}$$

Figure 19: Identifying the promotion function.

Composing the Result. The $\Gamma \vdash (T_A,\ T_B) \Downarrow_i t$ judgment consists of only INDEX-IND, which identifies the motive and each case using the other two judgments, then composes the result. In the case of `list` and `vector`, this produces a function that computes the length of a list:

```
λ (l:list T).Elim(l, λ (l:list T).nat)
  {0, λ (t_l:T) (l:list T) (IH_l:(λ (l:list T).nat) l).S IH_l}
```

4.3.3.2 *Searching for Promote and Forget*

Figure 19 shows the interesting derivations for the judgment $(T_A,\ T_B) \Downarrow_p t$ that searches for `promote`: PROMOTE-MOTIVE identifies the motive as B with a new index (which it computes using `indexer`, denoted by metavariable π). When PROMOTE-IH recurses, it substitutes the inductive hypothesis for the term rather than for its index, and it substitutes the new index (which it also computes using `indexer`) inside of that term. PROMOTE-CONCLUSION returns the entire term, rather than its index. Finally, PROMOTE-IND not only recurses into each case, but also packs the result.

The omitted derivations to search for `forget` are similar, except that the domain and range are switched. Consequentially, `indexer` is never needed; FORGET-MOTIVE removes the index rather than inserting it, and FORGET-IH no longer substitutes the index. Additionally, FORGET-HYPOTHESIS adds the hypothesis for the new index rather than skipping it, and FORGET-IND eliminates over the projection rather than packing the result.

CORE SEARCH ALGORITHM The core search algorithm produces `indexer`, `promote`, and `forget`, then composes them into a tuple. This tuple is how DEVOID represents ornaments internally. DEVOID has options (used in `Example.v`) that tell search to generate proofs that its outputs are correct, thereby increasing confidence in and usefulness of those outputs. The proof of `coherence` is reflexivity. The intuition behind the automation to prove `section` and `retraction` (`equivalence.ml`) is that `promote` and `forget` map along corresponding constructors, so inductive cases preserve equalities. Thus, each inductive case of these proofs is generated by a fold that rewrites each recursive reference, with reflexivity as identity.

4.3.3.3 *Other Search Procedures*

Brief explanation of these and how differencing works for them in detail based on algebraic ornaments

DESIGNING NEW SEARCH PROCEDURES How hard, how useful

4.3.4 *Limitations*

Limitations and whether they're addressed in other tools yet or not

4.4 TRANSFORMATION

Figure 25 shows the proof term transformation $\Gamma \vdash t \Uparrow t'$ that forms the core of PUMPKIN Pi. The transformation is parameterized over equivalent types A and B (EQUIVALENCE) as well as the configuration. It assumes η-expanded functions. It implicitly constructs an updated context Γ' in which to interpret t', but this is not needed for computation.

The proof term transformation is (perhaps deceptively) simple by design: it moves the bulk of the work into the configuration, and represents the configuration explicitly. Of course, typical proof terms in Coq do not apply these configuration terms explicitly. PUMPKIN Pi does some additional work using *unification heuristics* to get real proof terms into this format before running the transformation. It then runs the proof term transformation, which transports proofs across the equivalence that corresponds to the configuration.

Unification Heuristics. The transformation does not fully describe the search procedure for transforming terms that PUMPKIN Pi implements. Before running the transformation, PUMPKIN Pi *unifies* subterms with

$$\boxed{\Gamma \vdash t \Uparrow t'}$$

 } m.
```

Figure 21: Swapping cases of the append function, counterclockwise, the input term: 1) unmodified, 2) unified with the configuration, 3) ported to the updated type, and 4) reduced to the output.

particular A (fixing parameters and indices), and with applications of configuration terms over A. The transformation then transforms configuration terms over A to configuration terms over B. Reducing the result produces the output term defined over B.

Figure 21 shows this with the list append function ++ from Section 4.1. To update ++ (top left), Pumpkin Pi unifies `Old.list T` with A, and `Constr` and `Elim` with `DepConstr` and `DepElim` (bottom left). After unification, the transformation recursively substitutes B for A, which moves `DepConstr` and `DepElim` to construct and eliminate over the updated type (bottom right). This reduces to a term with swapped constructors and cases over `New.list T` (top right).

In this case, unification is straightforward. This can be more challenging when configuration terms are dependent. This is especially pronounced with definitional `Eta` and `Iota`, which typically are implicit (reduced) in real code. To handle this, Pumpkin Pi implements custom *unification heuristics* for each search procedure that unify subterms with applications of configuration terms, and that instantiate parameters and dependent indices in those subterms ⑥. The transformation in turn assumes that all existing parameters and indices are determined and instantiated by the time it runs.

Pumpkin Pi falls back to Coq's unification for manual configuration and when these custom heuristics fail. When even Coq's unification is not enough, Pumpkin Pi relies on proof engineers to provide hints in the form of annotations ⑤.

Algebraic Ornaments. Consider instantiating the transformation to algebraic ornaments. We show only one direction of the algorithm, promoting from A to packed B; the forgetful direction is similar. The

```
↑       {i⃗_a : X⃗_A} := promote i⃗_a.          ↓
          {i⃗_b : X⃗_B} := forget i⃗_b.
π_{I_B} {i⃗_a : X⃗_A} := indexer i⃗_a.          ∃_{I_B} {i⃗_b : X⃗_B} (b : B i⃗_b)
          := ∃ i⃗_b[off] b.
↑_B     := π_r ∘ ↑.                            ↓_A     := ↓ ∘ ∃_{I_B}.
↑_{I_B} := π_l ∘ ↑.                            ↓_{I_B} := π_{I_B} ∘ ↓_A.
```

Figure 22: Common definitions for the core lifting algorithm.

core algorithm (Figure 25) builds on a set of common definitions (Figure 22) and two intermediate judgments: one to lift eliminators (Figure 23) and one to lift constructors (Figure 24).

Common Definitions. The common definitions (Figure 22) define some useful syntax: $\uparrow$ applies `promote`, $\downarrow$ applies `forget`, and π_{I_B} applies `indexer`. $\exists_{I_B}$ packs a term of type B into an existential with the index at the appropriate offset. $\uparrow_B$ and $\uparrow_{I_B}$ promote and then project; $\downarrow_A$ packs and forgets, and $\downarrow_{I_B}$ packs, forgets, and then applies `indexer` to project the index.

LIFTING ELIMINATORS The $\Gamma \vdash t \Uparrow_E t'$ judgment (Figure 23) defines rules for lifting the motive and case of an eliminator, changing the *domain of induction* from A to B. The intuition is that any term of type A is the result of forgetting some term of type packed B. Then, since A and B have the same inductive structure, we can lift the eliminator of A to the eliminator of B, and move that forgetfulness *inside of each case*. For example, the following terms are propositionally equal:

```
Elim((↓_A b), p_A){
  f_nil,
  (λ(t_l:T)(l:list T)(IH_l:
      p_A l).
    f_cons t_l l IH_l)
}
```

```
Elim(b, λ(n:nat)(v:vector T n).p_A
    (↓_A v)){
  f_nil,
  (λ(n:nat)(t_v:T)(v:vector T n)(IH_v:p_A
      (↓_A v)).
    f_cons t_v (↓_A v) IH_v)
}
```

The induction rules implement this transformation. CASE lifts a case of the eliminator by first recursively lifting the motive, then using the lifted motive to compute the type of the new case, and then using that type to compute the body of the new case. In the example above, when lifting the inductive case, it first recursively lifts the motive p_A using MOTIVE, which drops the index, packs and forgets the argument of type B, and then β-reduces the result, eliminating references to B. This produces the new motive:

```
λ(n:nat)(v:vector T n).p_A (↓_A v)
```

which CASE then uses to compute the type of the inductive case of the eliminator for B:

```
Π(t_v:T)(n:nat)(v:vector T n)(IH_v:p_A (↓_A v)).p_A (↓_A (consV t_v (
    S n) v))
```

$$\boxed{\Gamma \vdash (t,\ T) \Uparrow_{E_x} t'}$$

$$\textsc{Drop-Index}\ \frac{\text{new}\ n\ b \qquad \Gamma,\ n : t \vdash (f,\ b) \Uparrow_{E_x} b'}{\Gamma \vdash (f,\ \Pi(n : t).b) \Uparrow_{E_x} \lambda(n : t).b'}$$

$$\textsc{Forget-Arg}\ \frac{\Gamma \vdash \vec{i} : \vec{X}_B \qquad \Gamma,\ n : B\ \vec{i} \vdash ((f\ (\downarrow_A n))_\beta,\ b) \Uparrow_{E_x} b'}{\Gamma \vdash (f,\ \Pi(n : B\ \vec{i}).b) \Uparrow_{E_x} \lambda(n : B\ \vec{i}).b'}$$

$$\boxed{\Gamma \vdash t \Uparrow_C t'}$$

$$\textsc{Normalize}\ \frac{}{\Gamma \vdash \text{Constr}(j,\ A)\ \vec{x} \Uparrow_C (\uparrow (\text{Constr}(j,\ A)\ \vec{x}))_{\beta\delta\iota}}$$

Figure 24: Lifting constructors.

The $\Gamma \vdash (t,\ T) \Uparrow_{E_x} t'$ judgment then uses that type to compute the lifted function body. It computes this in a similar way to Motive, except that there are as many indices to drop and arguments to pack and forget as there are inductive hypotheses, and these do not occur in predictable places, so more rules are involved. This computes the new function:

λ(n:nat)(t$_v$:T)(v:vector T n)(IH$_v$:p$_A$ ($\downarrow_A$ v)).f$_{\text{cons}}$ t$_v$ ($\downarrow_A$ v) IH$_v$

LIFTING CONSTRUCTORS The $\Gamma \vdash t \Uparrow_C t'$ judgment (Figure 24) lifts applications of constructors of A to applications of constructors of B. This judgment computes one step of the promotion, leaving the recursive lifting of the arguments to the final algorithm. Using the same types, in the base case:

$\uparrow$ nil $\equiv_{\beta\delta\iota}$ $\exists$ O nilV and in the inductive case:

$\uparrow$ `(cons t l)` $\equiv_{\beta\delta\iota}$ $\exists$ `(S (`$\uparrow_{I_B}$ `l)) (consV (`$\uparrow_{I_B}$ `l) t (`$\uparrow_B$ `l))`

This derivation consists of only one rule: Normalize, which normalizes the promotion of the constructor. This is guaranteed to succeed because the application of the constructor is fully η-expanded. The core algorithm later internalizes the promotion functions in the result.

CORE LIFTING ALGORITHM The core algorithm (Figure 25) builds on these intermediate judgments. The interesting derivations for correctness are the first six: Lift-Elim and Lift-Constr use the judgments for lifting eliminators and constructors of A. Internalize internalizes the explicit `promote` functions from the lifted constructors to recursive applications of the algorithm. Retraction and Coherence use the respective properties of the ornamental promotion isomorphism metatheoretically: the first to drop the explicit `forget` functions from the lifted eliminators, and the second to lift the `indexer` to a projection (in the forgetful direction, Section replaces Retraction). Finally, Equivalence lifts A along the equivalence to packed B. The remaining derivations recurse predictably.

Specifying a Correct Transformation. The implementation of this transformation in Pumpkin Pi produces a term that Coq type checks, and so does not add to the trusted computing base. As Pumpkin Pi is an engineering tool, there is no need to formally prove the transformation correct, though doing so would be satisfying. The goal of such a proof would be to show that if $\Gamma \vdash t \Uparrow t'$, then t and t' are equal up to transport, and t' refers to B in place of A. The key steps in this transformation that make this possible are porting terms along the configuration (Dep-Constr, Dep-Elim, Eta, and Iota). For metatheoretical reasons, without additional axioms, a proof of this theorem in Coq can only be approximated [82]. It would be possible to generate per-transformation proofs of correctness, but this does not serve an engineering need.

Figure 25: Core lifting algorithm.

4.5.2 *Workflow Integration*

4.5.2.1 *Configure*

4.5.2.2 *Transform*

Termination. When a subterm unifies with a configuration term, this suggests that Pumpkin Pi *can* transform the subterm, but it does not necessarily mean that it *should*. In some cases, doing so would result in nontermination. For example, if B is a refinement of A, then we can always run Equivalence over and over again, forever. We thus include some simple termination checks in our code (12).

Intent. Even when termination is guaranteed, whether to transform a subterm depends on intent. That is, Pumpkin Pi automates the case of porting *every* A to B, but proof engineers sometimes wish to port only *some* As to Bs. Pumpkin Pi has some support for this using an interactive workflow (13), with plans for automatic support in the future.

From CIC$_\omega$ to Coq. The implementation (4) of the transformation handles language differences to scale from CIC$_\omega$ to Coq. We use the existing `Preprocess` [78] command to turn pattern matching and fixpoints into eliminators. We handle refolding of constants in constructors using `DepConstr`.

Reaching Real Proof Engineers. Many of our design decisions in implementing Pumpkin Pi were informed by our partnership with an industrial proof engineer (Section 4.6). For example, the proof engineer rarely had the patience to wait more than ten seconds for Pumpkin Pi to port a term, so we implemented optional aggressive caching, even caching intermediate subterms encountered while running the transformation (14). We also added a cache to tell Pumpkin Pi not to δ-reduce certain terms (14). With these caches, the proof engineer found Pumpkin Pi efficient enough to use on a code base with tens of thousands of lines of code and proof.

The experiences of proof engineers also inspired new features. For example, we implemented a search procedure to generate custom eliminators to help reason about types like Σ`(l : list T).length l = n` by reasoning separately about the projections (15). We added informative error messages (22) to help the proof engineer distinguish between user errors and bugs. These features helped with workflow integration.

4.5.2.3 *Decompile*

Transform produces a proof term, while the proof engineer typically writes and maintains proof scripts made up of tactics. We improve usability thanks to the realization that, since Coq's proof term language

Figure 27: Qtac decompiler semantics.

Gallina is very structured, we can decompile these Gallina terms to suggested Ltac proof scripts for the proof engineer to maintain.

Decompile implements a prototype of this translation (11): it translates a proof term to a suggested proof script that attempts to prove the same theorem the same way. Note that this problem is not well defined: while there is always a proof script that works (applying the proof term with the `apply` tactic), the result is often qualitatively unreadable. This is the baseline behavior to which the decompiler defaults. The goal of the decompiler is to improve on that baseline as much as possible, or else suggest a proof script that is close enough to correct that the proof engineer can manually massage it into something that works and is maintainable.

Decompile achieves this in two passes: The first pass decompiles proof terms to proof scripts that use a predefined set of tactics. The second pass improves on suggested tactics by simplifying arguments, substituting tacticals, and using hints like custom tactics and decision procedures.

First Pass: Basic Proof Scripts. The first pass takes Coq terms and produces tactics in Ltac, the proof script language for Coq. Ltac can be confusing to reason about, since Ltac tactics can refer to Gallina terms, and the semantics of Ltac depends both on the semantics of Gallina and on the implementation of proof search procedures written in OCaml. To give a sense of how the first pass works without the clutter of these details, we start by defining a mini decompiler that implements a simplified version of the first pass. Section **??** explains how we scale this to the implementation.

The mini decompiler takes CIC_ω terms and produces tactics in a mini version of Ltac which we call Qtac. The syntax for Qtac is in Figure 26. Qtac includes hypothesis introduction (`intro`), rewriting (`rewrite`), symmetry of equality (`symmetry`), application of a term to prove the goal (`apply`), induction (`induction`), case splitting of conjunctions (`split`), constructors of disjunctions (`left` and `right`), and composition (`.`). Unlike in Ltac, `induction` and `rewrite` take a motive explicitly (rather than relying on unification), and `apply` creates a new subgoal for each function argument.

The semantics for the mini decompiler $\Gamma \vdash t \Rightarrow p$ are in Figure 27 (assuming $=$, `eq_sym`, $\wedge$, and $\vee$ are defined as in Coq). As with the real decompiler, the mini decompiler defaults to the proof script that applies the entire proof term with `apply` (Base). Otherwise, it improves on that behavior by recursing over the proof term and constructing a proof script using a predefined set of tactics.

For the mini decompiler, this is straightforward: Lambda terms become introduction (Intro). Applications of `eq_sym` become symmetry of equality (Symmetry). Constructors of conjunction and disjunction map to the respective tactics (Split, Left, and Right). Applications of equality eliminators compose symmetry (to orient the rewrite direc-

  + simpl. rewrite app_nil_r. auto.
  + auto.
```

Figure 28: Proof term (top) and decompiled proof script (bottom) for the base case of rev_app_distr (Section 4.1), with corresponding terms and tactics grouped by color & number.

tion) with rewrites (Rewrite), and all other applications of eliminators become induction (Induction). The remaining applications become apply tactics (Apply). In all cases, the decompiler recurses, breaking into cases, until only the Base case holds.

While the mini decompiler is very simple, only a few small changes are needed to move this to Coq. The generated proof term of rev_app_distr from Section 4.1, for example, consists only of induction, rewriting, simplification, and reflexivity (solved by auto). Figure 28 shows the proof term for the base case of rev_app_distr alongside the proof script that Pumpkin Pi suggests. This script is fairly low-level and close to the proof term, but it is already something that the proof engineer can step through to understand, modify, and maintain. There are few differences from the mini decompiler needed to produce this, for example handling of rewrites in both directions (eq_ind_r as opposed to eq_ind), simplifying rewrites, and turning applications of eq_refl into reflexivity or auto.

Second Pass: Better Proof Scripts. The implementation of **Decompile** first runs something similar to the mini decompiler, then modifies the suggested tactics to produce a more natural proof script (11). For example, it cancels out sequences of intros and revert, inserts semicolons, and removes extra arguments to apply and rewrite. It can also take tactics from the proof engineer (like part of the old proof script) as hints, then iteratively replace tactics with those hints, checking for correctness. This makes it possible for suggested scripts to include custom tactics and decision procedures.

From Qtac to Ltac. The mini decompiler assumes more predictable versions of rewrite and induction than those in Coq. **Decompile** includes additional logic to reason about these tactics (11). For example, Qtac assumes that there is only one rewrite direction. Ltac has two rewrite directions, and so the decompiler infers the direction from the motive.

Qtac also assumes that both tactics take the inductive motive explicitly, while in Coq, both tactics infer the motive automatically. Consequentially, Coq sometimes fails to infer the correct motive. To handle induction, the decompiler strategically uses `revert` to manipulate the goal so that Coq can better infer the motive. To handle rewrites, it uses `simpl` to refold the goal before rewriting. Neither of these approaches is guaranteed to work, so the proof engineer may sometimes need to tweak the suggested proof script appropriately. Even if we pass Coq's induction principle an explicit motive, Coq still sometimes fails due to unrepresented assumptions. Long term, using another tactic like `change` or `refine` before applying these tactics may help with cases for which Coq cannot infer the correct motive.

From CIC$_\omega$ to Coq. Scaling the decompiler to Coq introduces let bindings, which are generated by tactics like `rewrite in`, `apply in`, and `pose`. **Decompile** implements (11) support for `rewrite in` and `apply in` similarly to how it supports `rewrite` and `apply`, except that it ensures that the unmanipulated hypothesis does not occur in the body of the let expression, it swaps the direction of the rewrite, and it recurses into any generated subgoals. In all other cases, it uses `pose`, a catch-all for let bindings.

Forfeiting Soundness. While there is a way to always produce a correct proof script, **Decompile** deliberately forfeits soundness to suggest more useful tactics. For example, it may suggest the `induction` tactic, but leave the step of motive inference to the proof engineer. We have found these suggested tactics easier to work with (Section 4.6). Note that in the case the suggested proof script is not quite correct, it is still possible to use the generated proof term directly.

Pretty Printing. After decompiling proof terms, **Decompile** pretty prints the result (11). Like the mini decompiler, **Decompile** represents its output using a predefined grammar of Ltac tactics, albeit one that is larger than Qtac, and that also includes tacticals. It maintains the recursive proof structure for formatting. Pumpkin Pi keeps all output terms from **Transform** in the Coq environment in case the decompiler does not succeed. Once the proof engineer has the new proof, she can remove the old one.

4.6 RESULTS

This section summarizes eight case studies using Pumpkin Pi, corresponding to the eight rows in Table 1. These case studies highlight Pumpkin Pi's flexibility in handling diverse scenarios, the success of automatic configuration for better workflow integration, the preliminary success of the prototype decompiler, and clear paths to better serving proof engineers. Detailed walkthroughs are in the code.

Algebraic Ornaments: Lists to Packed Vectors. The transformation in Pumpkin Pi is a generalization of the transformation from Devoid. Devoid supported proof reuse across *algebraic ornaments*, which describe relations between two inductive types, where one type is the

Figure 29: A simple language (left) and the same language with two swapped constructors and an added constructor (right).

other indexed by a fold [59]. A standard example is the relation between a list and a length-indexed vector (Figure 11).

Pumpkin Pi implements a search procedure for automatic configuration of algebraic ornaments. The result is all functionality from Devoid, plus tactic suggestions. In file ③, we used this to port functions and a proof from lists to vectors of *some* length, since `list T` $\simeq$ `packed_vect T`. The decompiler helped us write proofs in the order of hours that we had found too hard to write by hand, though the suggested tactics did need massaging.

Unpack Sigma Types: Vectors of Particular Lengths. In the same file ③, we then ported functions and proofs to vectors of a *particular* length, like `vector T n`. Devoid had left this step to the proof engineer. We supported this in Pumpkin Pi by chaining the previous change with an automatic configuration for unpacking sigma types. By composition, this transported proofs across the equivalence from Section **??**.

Two tricks helped with workflow integration for this change: 1) have the search procedure view `vector T n` as Σ`(v : vector T m).n = m` for some `m`, then let Pumpkin Pi instantiate those equalities via unification heuristics, and 2) generate a custom eliminator for combining list terms with length invariants. The resulting workflow works not just for lists and vectors, but for any algebraic ornament, automating manual effort from Devoid. The suggested tactics were helpful for writing proofs in the order of hours that we had struggled with manually over the course of days, but only after massaging. More effort is needed to improve tactic suggestions for dependent types.

Tuples & Records: Industrial Use. An industrial proof engineer at the company Galois has been using Pumpkin Pi in proving correct an implementation of the TLS handshake protocol. Galois had been using a custom solver-aided verification language to prove correct C programs, but had found that at times, the constraint solvers got stuck. They had built a compiler that translates their language into Coq's specification language Gallina, that way proof engineers could finish stuck proofs interactively using Coq. However, due to language differences, they had found the generated Gallina programs and specifications difficult to work with.

The proof engineer used Pumpkin Pi to port the automatically generated functions and specifications to more human-readable functions and specifications, wrote Coq proofs about those functions and specifications, then used Pumpkin Pi to port those proofs back to proofs about the original functions and specifications. So far, they have used at least three automatic configurations, but they most often used an automatic configuration for porting compiler-produced anonymous tuples to named records, as in file (18). The workflow was a bit nonstandard, so there was little need for tactic suggestions. The proof engineer reported an initial time investment learning how to use Pumpkin Pi, followed by later returns.

Permute Constructors: Modifying a Language. The swapping example from Section 4.1 was inspired by benchmarks from the Replica user study of proof engineers [76]. A change from one of the benchmarks is in Figure 29. The proof engineer had a simple language represented by an inductive type `Term`, as well as some definitions and proofs about the language. The proof engineer swapped two constructors in the language, and added a new constructor `Bool`.

This case study and the next case study break this change into two parts. In the first part, we used Pumpkin Pi with automatic configuration to repair functions and proofs about the language after swapping the constructors (1). With a bit of human guidance to choose the permutation from a list of suggestions, Pumpkin Pi repaired everything, though the original tactics would have also worked, so there was not a difference in development time.

Add new Constructors: Extending a Language. We then used Pumpkin Pi to repair functions after adding the new constructor in Figure 29, separating out the proof obligations for the new constructor from the old terms (19). This change combined manual and automatic configuration. We defined an inductive type `Diff` and (using partial automation) a configuration to port the terms across the equivalence `Old.Term + Diff` $\simeq$ `New.Term`. This resulted in case explosion, but was formulaic, and pointed to a clear path for automation of this class of changes. The repaired functions guaranteed preservation of the behavior of the original functions.

Adding constructors was less simple than swapping. For example, Pumpkin Pi did not yet save us time over the proof engineer from the user study; fully automating the configuration would have helped significantly. In addition, the repaired terms were (unlike in the swap case) inefficient compared to human-written terms. For now, they make good regression tests for the human-written terms—in the future, we hope to automate the discovery of the more efficient terms, or use the refinement framework CoqEAL [21] to get between proofs of the inefficient and efficient terms.

Factor out Constructors: External Example. The change from Figure 10 came at the request of a non-author. We supported this using a manual configuration that described which constructor to map to `true` and which constructor to map to `false` (2). The configuration was very simple for us to write, and the repaired tactics were immediately useful. The development time savings were on the order of minutes for a small proof development. Since most of the modest development time went into writing the configuration, we expect time savings would increase for a larger development.

Permute Hypotheses: External Example. The change in (20) came at the request of a different non-author (a cubical type theory expert), and shows how to use Pumpkin Pi to swap two hypotheses of a type, since $\texttt{T1} \rightarrow \texttt{T2} \rightarrow \texttt{T3} \simeq \texttt{T2} \rightarrow \texttt{T1} \rightarrow \texttt{T3}$. This configuration was manual. Since neither type was inductive, this change used the generic construction for any equivalence. This worked well, but necessitated some manual annotation due to the lack of custom unification heuristics for manual configuration, and so did not yet save development time, and likely still would not have had the proof development been larger. Supporting custom unification heuristics would improve this workflow.

Change Inductive Structure: Unary to Binary. In (5), we used Pumpkin Pi to support a classic example of changing inductive structure: updating unary to binary numbers, as in Figure 14. Binary numbers allow for a fast addition function, found in the Coq standard library. In the style of Magaud & Bertot 2000 [57], we used Pumpkin Pi to derive a slow binary addition function that does not refer to `nat`, and to port proofs from unary to slow binary addition. We then showed that the ported theorems hold over fast binary addition.

The configuration for `N` used definitions from the Coq standard library for `DepConstr` and `DepElim` that had the desired behavior with no changes. `Iota` over the successor case was a rewrite by a lemma from the standard library that reduced the successor case of the eliminator that we used for `DepElim`:

```
N.peano_rect_succ : ∀ P pO pS n,
  N.peano_rect P pO pS (N.succ n) =
  pS n (N.peano_rect P pO pS n).
```

The need for nontrivial `Iota` comes from the fact that `N` and `nat` have different inductive structures. By writing a manual configuration with this `Iota`, it was possible for us to implement this transformation that had been its own tool.

While porting addition from `nat` to `N` was automatic after configuring Pumpkin Pi, porting proofs about addition took more work. Due to the lack of unification heuristics for manual configuration, we had to annotate the proof term to tell Pumpkin Pi that implicit casts in the inductive cases of proofs were applications of `Iota` over `nat`. These annotations were formulaic, but tricky to write. Unification heuristics would go a long way toward improving the workflow.

After annotating, we obtained automatically repaired proofs about slow binary addition, which we found simple to port to fast binary addition. We hope to automate this last step in the future using CoqEAL. Repaired tactics were partially useful, but failed to understand custom eliminators like `N.peano_rect`, and to generate useful tactics for applications of `Iota`; both of these are clear paths to more useful tactics. The development time for this proof with PUMPKIN Pi was comparable to reference manual repairs by external proof engineers. Custom unification heuristics would help bring returns on investment for experts in this use case.

4.7 CONCLUSION

Rehashing thesis and how we do it

What we got here beyond what we had in PUMPKIN PATCH, segue into next chapter

5

RELATED WORK

5.1 PROGRAMS

Program Refactoring

Refactoring [63].

Program Repair

Adapting proofs to changes is essentially program repair for dependently typed languages. Program repair tools for languages with non-dependent type systems [72, 55, 52, 61, 67] may have applications in the context of a dependently typed language. Similarly, our work may have applications within program repair in these languages: Future applications of our approach may repurpose it to repair programs for functional languages.

Ornaments

Devoid automates discovery of and lifting across algebraic ornaments in a higher-order dependently typed language. In the decade since the discovery of ornaments [59], there have been a number of formalizations and embedded implementations of ornaments [27, 48, 28, 49, 26]. Devoid is the first tool for ornamentation to operate over a non-embedded dependently typed language. It essentially moves the automation-heavy approach of Ornamentation in ML [86], which operates on non-embedded ML code, into the type theory that forms the basis of theorem provers like Coq. In doing so, it takes advantage of the properties of algebraic ornaments [59]. It also introduces the first search algorithm to identify ornaments, which in the past was identified as a "gap" in the literature [49].

Programming by Example

Our approach generalizes an example that the programmer provides. This is similar to programming by example, a subfield of program synthesis [41]. This field addresses different challenges in different logics, but may drive solutions to similar problems in a dependently typed language.

Differencing & Incremental Computation

Existing work in differencing and incremental computation may help improve our semantic differencing component. Type-directed diffing [66] finds differences in algebraic data types. Semantics-based change impact analysis [5] models semantic differences between documents. Differential assertion checking [51] analyzes different versions of a program for relative correctness with respect to a specification. Incremental λ-calculus [14] introduces a general model for program changes. All of these may be useful for improving semantic differencing.

5.2 PROOFS

Proof Reuse

Our approach reimagines the problem of proof reuse in the context of proof automation. While we focus on changes that occur over time, traditional proof reuse techniques can help improve our approach. Existing work in proof reuse focuses on transferring proofs between isomorphisms, either through extending the type system [8] or through an automatic method [58]. This is later generalized and implemented in Isabelle [43] and Coq [88, 81]; later methods can also handle implications. Integrating a transfer tactic with a proof patch finding tool will create an end-to-end tool that can both find patches and apply them automatically.

Proof reuse for extended inductive types [10] adapts proof obligations to structural changes in inductive types. Later work [68] proposes a method to generate proofs for new constructors. These approaches may be useful when extending the differencing component to handle structural changes. Existing work in theorem reuse and proof generalization [36, 73, 46] abstracts existing proofs for reusability, and may be useful for improving the abstraction component. Our work focuses on the components critical to searching for patches; these complementary approaches can drive improvements to the components.

Devoid identifies and lifts proofs along a specific equivalence similar to that from existing ornaments work [49]. The need to automatically lift functions and proofs across equivalences and other relations is a long-standing challenge for proof engineers [57, 9, 56, 44, 89, 22]. The univalence axiom from Homotopy Type Theory [85] enables transparent transport of proofs; cubical type theory [20] gives univalence a constructive interpretation.

Similarly, our work is related to CoqEAL [22], which transfers functions along arbitrary relations between types. As these relations do not necessarily need to be equivalences, this framework is more general than our work. Similar tradeoffs between automation and generality apply: CoqEAL produces functions that refer to the old type, and does not yet support automatic inference of relations. In addition, CoqEAL currently only supports automatic transfer of functions, and does not yet handle proofs.

These tools may provide an alternative backend for Devoid. Furthermore, our search algorithm may help discover relations that make these tools easier to use, and our lifting algorithm may help improve automation and efficiency for certain relations in these tools.

The problem that we solve is fundamentally about proof reuse, which applies software reuse principles to ITPs. There is a wealth of work in proof reuse, from tactic languages [37] and logical frameworks [15], to tools for proof abstraction and generalization [74, 47], to domain-specific methodologies [29] and frameworks [30].

Devoid focuses on the specific problem of reuse when adding fully-determined indices to types. Other approaches to this problem include combinators which definitionally reduce to desirable terms [35] in the language Cedille, and automatic generation of conversion functions in Ghostbuster [60] for GADTs in Haskell. Our work focuses on a type theory different from both of these, in which the properties that allow for such combinators in Cedille are not present, and in which dependent types introduce challenges not present in Haskell.

Devoid is not the first tool to combine search with reuse. Optician [65] synthesizes bidirectional string transformations; a similar approach may help extend tooling to handle transformations for low-level data. Pumpkin Patch [77] searches the difference in proofs for patches that can be used to repair proofs broken by changes; Devoid uses a similar approach to identify functions that form an equivalence. The resulting tools are complementary: Devoid supports the addition of indices and hypotheses, which Pumpkin Patch does not support; Pumpkin Patch supports changes in values, which Devoid does not support.

Proof Evolution

There is a small body of work on change and dependency management for verification, both to evaluate impact of potential changes and maximize reuse [45, 4] and to optimize build performance [16]. These approaches may help isolate changes, which is necessary to identify future benchmarks, integrate with CI systems, and fully support version updates.

Proof Refactoring

Proof Repair

Proof Design

Existing proof engineering work addresses brittleness by planning for changes [87] and designing theorems and proofs that make maintenance less of an issue. Design principles for specific domains (such as formal metatheory [6, 31, 32]) can make verification more tractable. CertiKOS [40] introduces the idea of a deep specification to ease verification of large systems. These design principles and frameworks are complementary to our approach. Even when programmers use informed design principles, changes outside of the programmer's control can break proofs; our approach addresses these changes.

Proof Automation

We address a missed opportunity in proof automation for ITP: searching for patches that can fix broken proofs. This is complementary to existing automation techniques. Nonetheless, there is a wealth of work in proof automation that makes proofs more resilient to change. Powerful tactics like `crush` [18] can make proofs more resilient to changes. Hammers like Isabelle's sledgehammer [71] can make proofs agnostic to some low-level changes. Recent work [25] paves the way for a hammer in Coq. Even the most powerful tactics cannot address all changes; our hope is to open more possibilities for automation.

Powerful project-specific tactics [18, 17] can help prevent low-level maintenance tasks. Writing these tactics requires good engineering [39] and domain-specific knowledge, and these tactics still sometimes break in the face of change. A future patching tool may be able to repair tactics; the debugging process for adapting a tactic is not too dissimilar to providing an example to a tool.

Rippling [13] is a technique for automating inductive proofs that uses restricted rewrite rules to guide the inductive hypothesis toward the conclusion; this may guide improvements to the differencing, abstraction, and specialization components. The abstraction and factoring components address specific classes of unification problems; recent developments to higher-order unification [64] may help improve these components. Lean [80] introduces the first congruence closure algorithm for dependent type theory that relies only on the Uniqueness of Identity Proofs (UIP) axiom. While UIP is not fundamental to Coq, it is frequently assumed as an axiom; when it is, it may be tractable to use a similar algorithm to improve the tool.

GALILEO [12] repairs faulty physics theories in the context of a classical higher-order logic (HOL); there is preliminary work extending this style of repair to mathematical proofs. Knowledge-sharing methods [38] can adapt some proofs across different representations of HOL. These complementary approaches may guide extensions to support decidable domains and classical logics.

6

CONCLUSIONS & FUTURE WORK

Reflect on thesis statement and explain how we got it exactly now that you know everything

But I want to spend the resst of this thesis talking about the next era of verification so I can write out a bunch of ideas for students who might want to work with me

THE NEXT ERA: PROOF ENGINEERING FOR ALL

Future Work from many papers, plus research statement, DARPA thoughts, plus more, but trimmed down a lot

What I want in the long run, how this all fits in, is a world of proof engineering for all. From research statement, three rings (four including experts in the center).

And what we have so far with my thesis is a world where it's easier for experts and a bit easier for practitioners, but there's still a lot left to go building on it.

So here are 12 short future project summaries that reach each of these tiers, building that world. Super please contact me if any of these seem fun to you.

Proof Engineering for Experts

Unifying theme: lateral reach. Some examples:

MORE PROOF ASSISTANTS Thoughts from PUMPKIN Pi on Isabelle/HOL, future work from PUMPKIN PATCH.

MORE CHANGES Version updates, isolating large changes (PUMPKIN PATCH), relations more general than equivalences (PUMPKIN Pi).

MORE STYLES ML for decompiler (PUMPKIN Pi, REPLICA) : more for diverse proof styles (PUMPKIN PATCH). Note that this is a WIP, but sketch out project, challenges, future ideas, expectations, evaluation a bit.

Proof Engineering for Practitioners

Unifying theme: usability. Some examples:

AUTOMATION More search procedures for automatic configuration, e-graphs from PUMPKIN Pi, custom unification heuristics.

INTEGRATION IDE & CI integration, HCI for repair.

EVALUATION repair challenge, user studies ideas (PUMPKIN PATCH, REPLICA, panel w/ Benjamin Pierce, QED at large). (maybe look for more ideas, this can be merged with integration if need be).

Proof Engineering for Software Engineers

Unifying theme: mixed methods verification, or the 2030 vision from Twitter thread. Some examples:

GRADUAL VERIFICATION A continuum from testing to verification, tools to help with that.

TOOL-ASSISTED PROOF DEVELOPMENT Tool-assisted development to follow good design principles for verificattion (James Wilcox conversation, final REPLICA takeaway).

SPECIFICATION INFERENCE Analysis to infer specs (TA1).

Proof Engineering for New Domains

Unifying theme: collaboration, new abstractions for new domains). Some examples:

MACHINE LEARNING Fairification & other ML correctness properties. Some stuff here but more.

CRYPTOGRAPHY Lots of stuff here but not thinking broadly enough. What about cryptographic proof systems? ZK and beyond. Recall email thread.

SOMETHING ELSE Look for more in survey paper, email, DARPA TAs, Twitter. Healthcare perhaps?
